Mayo Foundation Fellowships—The Mayo Foundation for Medical Education and Research, Rochester, Minnesota; D. C. Balfour, director; three-year fellowships, beginning quarterly, leading to the degree of M.S. or Ph.D. with field named from the University of Minnesota: in Anesthesia, Dermatology and Syphilology, Internal Medicine, Neurology and Psychiatry, Neurosurgery, Obstetrics and Gynecology, Ophthalmology, Orthopedic Surgery, Otolaryngology, Pathology, Pediatrics, Physical Medicine, Plastic Surgery, Proctology, Radiology, Surgery, Urology; stipend \$900 per year, (clinical fellowships including pathology and radiology—278).

- Compensation arranged by medical school and hospital.
- Represents number of patients.
- In lieu of maintenance.
- Outpatient and home delivery service only.
- Hospital facilities by affiliation.
- Resident selected and paid by Otho S. A. Sprague Memorial Institute.
- Includes residencies, assistant residencies and straight internships following previous intern training.
- Includes ophthalmologic patients.
- Includes otolaryngologic patients.
- Includes two fellowships in gastroenterology.
- Includes four one-year fellowships in gastroenterology.
- Residencies open to women.
- Residencies for women only.
- Inpatients: Numbers refer to total inpatients treated in specialty.
- Obstetrical admissions do not include newborns. In pathology and anesthesiology total hospital admissions are used.
- The percentage of free patients refers to the entire hospital service.
- Deaths and autopsies are reported for individual specialties. In obstetrics only maternal deaths are included; in anesthesiology, pathology and radiology all hospital deaths are listed exclusive of stillbirths.
- Chicago Lying-In Hospital and Dispensary, Chicago.
- Hospital service confined to drug addicts.
- Palmer Memorial Unit.
- Includes neurosurgery.
- Address all applications to superintendent.
- Maternity service at Herman Kiefer Hospital.

- Includes neurology.
- Hospital appoints residents from its own house staff.
- Includes orthopedics.
- Includes obstetrics.
- Applications will be considered only from men who have had a previous year's training in some recognized pathological laboratory.
- Apply to chief of service for information about affiliating hospitals.
- Includes proctology.
- Admissions confined to children.
- Separate appointments approved in roentgenology and radium therapy.
- Several services include obstetrics-gynecology.
- Includes thoracic surgery.
- Private and semi-private pavilions.
- Includes dermatology.
- Dental as well as medical degree required.
- Includes gynecology.
- Two residents serve six months on obstetrics.
- Includes x-ray and radium therapy.
- Affiliated with Free Hospital for Women, Brookline, Mass.
- Affiliated with Bishop De Goesbriand Hospital, Burlington, and Fanny Allen Hospital, Winoski.
- Mixed residencies represent general hospital experience of at least one year's duration following an approved internship. All hospitals approved for intern training are also certified for general or mixed residencies.

SATURDAY, AUGUST 31, 1940

THE PLATFORM OF THE AMERICAN
MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

INTERNSHIPS

The internship is an established institution in this country, mutually profitable to both hospitals and interns. Each year more hospitals seek the privilege of instructing interns. Even in those states in which an internship is not legally required for licensure, practically all medical graduates voluntarily serve this form of apprenticeship. The merits of "straight," "mixed" and "rotating" internships are still debated; probably all of these types are desirable and no one of them should be adopted to the exclusion of others.

Elsewhere in this issue Dr. William Dock¹ discusses the selection of interns and argues that medical students should secure intern appointments largely through their own efforts rather than through the agency of the dean or intern committee. Dr. Dock points out that assumption of responsibility for placing its graduates or fifth year students by the school incurs an obligation to those

1. Dock, William: Responsibility for Choosing Interns and Internships, this issue, p. 657.

hospitals which benevolently accept candidates who rank among the lowest in their class. Having recommended such a man in the fall of his final year, the faculty would scarcely dare to flunk him in June. A fortiori, medical schools should not make the internship a part of their requirement for a degree. Although twenty-five years has elapsed since such a requirement was first adopted at Minnesota, only 17 per cent² of the schools now make an internship obligatory. Certainly it cannot be said that there is any trend toward the inclusion of the internship in the undergraduate medical course.

In order to raise the standards of medical practice and, more particularly, to increase the educational value of internships the universities should, according to Dr. Dock, first clean their own house and raise the quality of the services in the hospitals which they control by inaugurating a more stringent selection of interns and residents and by opening these opportunities to wider competition. He deplores the inbreeding which now too often prevails. In conclusion he states that, "As long as the university attempts to guide or assist the student, this freedom of choice is restricted and the result is harmful to students and to medical schools."

VITAMIN DEFICIENCY AND MYO-
NEURAL RESISTANCE

According to experimental data currently reported by Sabin and Duffy¹ of the Children's Hospital, University of Cincinnati, dietary deficiencies in nursing mothers may retard the development of effective constitutional barriers against virus infections in nursing young, even though there is no retardation of normal growth or weight.

About four years ago it was shown by Olitsky and his co-workers² of the Rockefeller Institute that in growing mice there is an acquired resistance to viruses not associated with the presence or absence of humoral antibodies. This was shown in its most striking form on injection of massive doses of the virus of vesicular stomatitis. In mice 2 weeks of age, injected intramuscularly, almost 100 per cent develop fatal paralyses. With 3 week mice there are 85 per cent of fatalities, decreasing to about 15 per cent of mortality by the fourth week. Mice over 6 weeks of age are 100 per cent resistant to this type of injection. No maturation immunity is demonstrable on intracerebral injection, and there are no demonstrable virucidal antibodies. Maturation resistance is apparently due to development of an effective constitutional barrier at the myoneural junction.

Determination of the effect of nutritional factors on this myoneural maturation was attempted by the Cincinnati pediatricians. Because mice continue to suckle their young for about twenty-eight days, Sabin and his

2. Three schools have recently discarded the intern requirement.

1. Sabin, Albert B., and Duffy, Carl E.: Science 91: 532 (June 7) 1940.

2. Olitsky, P. K.; Sabin, A. B., and Cox, H. R.: J. Exper. Med. 61: 723 (Nov.) 1936.

colleagues first studied the effect of nutritional deficiencies in nursing mothers. Female mice were maintained on an "adequate" diet throughout pregnancy and for two days after delivery. On the second day, groups of these nursing mothers were placed on vitamin deficient diets. The breast fed young were tested at various age levels for the efficiency of their myoneural virus defense.

Control groups in which "adequate" maternal diet was continued during the twenty-eight day nursing period showed a normal development of myoneural resistance. With maternal diets deficient in vitamin E or in certain components of the vitamin B complex there was a definite retardation in the normal development of the myoneural barrier. The greatest retardation was noted in groups of sucklings in which the maternal diet had been partially denatured by overcooking (auto-claving).

In their second method of study the young of nursing mothers on adequate diets were weaned on the fourteenth day and placed on various deficiency rations. Control young placed on adequate rations made a good gain in weight and showed a normal development of virus resistance. With vitamin deficient rations, however, the young might have a normal increase in size or weight, but without exception they showed a well marked retardation in development of the myoneural defense.

In 6 week mice reared on adequate diets it has not yet proved possible to break down the matured virus barrier by subsequent vitamin deficiencies. The virus barrier remains wholly effective even after these mice have developed signs of advanced vitamin B₁, E or riboflavin deficiency.

THE NON COMPOS MENTIS TREATMENT OF APPENDICITIS

A recent issue of an extraordinary publication called the *Journal of Drugless Physicians* contains an article entitled "Appendicitis and Its Cure" by one Richard Van Rump, PH.C. (what is a PH.C.?), of New York City. "In this treatise," he begins, "we will not discuss causes, pathology and theories. We will discuss the Chiropractic and other manipulative treatment." He then disregards pathology entirely and suggests a manipulative treatment for a serious surgical condition, saying:

The methods to be described will be for acute appendicitis only. By "acute" we mean a typical case, with fever, pain, high white blood count, etc. Let us proceed. We are called to the bedside of a patient suffering with an unmistakable attack of acute appendicitis. The first thing we do after making our thorough physical, laboratory and Chiropractic examination, is to test the Vagus nerve against the appendiceal pain to see if the pain is of vagus origin.

Pressure at the atlas axis area slows down and inhibits the Vagus, which is stimulatory below the diaphragm and also influences the spinal accessory, which is motor to the Vagus nerve. This atlas axis pressure is held until the appendiceal pain clears—from one to three minutes. If after three minutes of pressure the appendix pain remains, it is proof sufficient that this particular case of appendicitis is not of Vagus origin.

Evidently at this point the weirdness of the author's notions caught up with him and he began to mistrust himself. So he continues:

Some might argue, why not adjust the atlas or axis instead of just using inhibition? I do not object to adjusting this area if you so prefer, providing your adjustment is more inhibitory than stimulatory. I sincerely believe that by using the Vagus inhibitory technic as described, you will be taking less of a chance.

Having thus disposed of risk in his own mind, Van Rump, PH.C., offers an alternative:

Preferred method number two in the treatment of appendicitis is the localizing method, a la DeJarnette. This method is used whenever there is a direct spinal nerve involvement. Your writer is well aware of the fact that the spinal nerves do not directly supply the appendix with nerve supply. Your writer also knows that the pain of appendicitis is not felt in the appendix itself, but rather in the tissues overlying the appendix, which tissues are supplied by the spinal nerve.

His scientific status now becomes wholly clear. With startling nonchalance he exploits his ignorance:

A special effort is being made in the writing of this article to avoid anatomy, pathology, etc., and keep it therapeutically Chiropractic.

In this avoidance of anatomy, pathology, etc., particularly etc., he is completely successful. The author admits, however, that

The localizing method of treating appendicitis will only work when the engorgement at the appendiceal region has referred caused an engorgement to exist within the nerve sheath at the 2nd lumbar nerve. We mention the 2nd lumbar nerve specifically because we of the Sacro Occipital Research Society have found that we persistently find this engorgement in all cases of appendicitis with direct spinal nerve involvement. We proceed as follows. . . . The patient's head is turned slightly to take out the slack, similar to giving a cervical break [whether a "cervical break" is to be preferred to appendicitis has not been determined.—Ed.] or rotation adjustment. In adjusting the occiput care must be taken that the chin is not rotated with the neck. [This sounds like a dislocated jaw.—Ed.] In other words, the chin must face straight up to the ceiling. When all the cervical slack is taken up and the chin facing the ceiling, a thrust is given directly on the occipital area that controlled all inferior pain.

Perhaps at this point the patient becomes unconscious or if still conscious leaves the table—the chiropractic table. But if he stays he finds out he is only beginning: . . . "Adjusting the occiput in acute appendicitis, or any other acute pain, will do no good unless it is the lesion that is causing the acute pain," says Van Rump, PH.C. But there is also a third method: "Place patient on the left side and bend the right knee onto the abdomen. . . . The technic, after proper contacts are made, is to pull the 2nd lumbar contact toward the operator while pushing the shoulder away from operator. When the contacts and thrusts are properly made, the characteristic Chiropractic pop will be heard." Perhaps the pop is the appendix rupturing! But this method is to be used only "if and when the two previous methods fail." And now Van Rump, PH.C., plays his ace: "Your writer strongly suggests that if the three methods described above fail to control the appendiceal pain, you call a surgeon at once [italics ours.—Ed.]. Your writer knows of other methods that

could be used, possibly successfully, but prefers not to use them or discuss them here, for safety's sake." Congratulations, Van Rumpt, PH.C., on calling a surgeon! We only hope it is not too late!!

Current Comment

LIFE AND OSTEOPATHY

In *Life*, which is a picture magazine, for August 19 appears an article entitled "Osteopathy's 'Cure-By-Manipulation' Is Attacked by Regular Physicians." Here a small amount of text is supplemented by a number of photographs, evidently made in or supplied through the osteopathic shrine at Kirksville, Mo., known as the Kirksville College of Osteopathy and Surgery. In the very brief text which accompanies the pictures appear a number of misstatements of fact which, it is not too confidently expected, the magazine may correct. Many of these misrepresentations have been repeatedly exposed in *THE JOURNAL*. In the second paragraph of the article, for example, appears this statement:

In 33 States qualified doctors of osteopathy are permitted to practice on equal or almost equal footing with doctors of medicine. Osteopaths can and do deliver babies, perform surgery, prescribe drugs and take full charge of patients.

The facts are that in only four states (Colorado, Massachusetts, New Hampshire and Texas) for certain, and perhaps in a fifth (Kentucky), may osteopaths now legally prescribe or dispense drugs without restriction. This is true in the first four states mentioned because in those states osteopathic applicants, if licensed at all, must meet the requirements exacted of applicants to practice medicine generally. To this list may be added, after Nov. 1, 1941, a sixth state (New Jersey), where osteopaths licensed after that date will be subject to the same requirements as nonsectarian applicants and will receive an unlimited license to practice medicine. Experience has shown that few osteopaths indeed are able to meet the requirements exacted of applicants to practice medicine generally. In twelve states osteopaths are given limited right to use certain drugs, the drugs concerned varying in the various states. In eight states osteopathic licentiates generally may not use drugs, but the laws contain provisions whereby osteopaths may, under certain conditions, obtain licenses by virtue of which they may use drugs, the law of one of these states even then permitting the use only of a very limited number of drugs. In eight states osteopaths are specifically denied the right to use drugs. In nine states osteopaths secure licenses only to practice osteopathy, without defining the scope of the practice permitted, but no court has ever held that the right to practice osteopathy includes the right to use drugs. In seven states osteopaths are licensed to practice osteopathy as taught in recognized schools of osteopathy which, in effect, denies them the use of drugs, and the Supreme Court of Kansas has recently held that the right to practice osteopathy as taught and practiced in recognized schools of osteopathy confers no right on osteopaths to practice operative surgery or to use remedial drugs. To summarize: In twenty-four states osteopaths

legally cannot under any circumstances use drugs. In eight states by far the greatest number of osteopaths cannot use drugs but it is possible for candidates possessing stated qualifications to obtain that right. In twelve states osteopaths may utilize stated drugs to a limited extent. Only in five states, probably, may osteopaths use drugs without restriction. Obviously, then, from the standpoint of the right to use drugs, which an osteopath must possess if he is "to practice on equal or almost equal footing with doctors of medicine," the article in *Life* is, to put it charitably, indulging in gross exaggeration when it states "In 33 States qualified doctors of osteopathy are permitted to practice on equal or almost equal footing with doctors of medicine."

RESIDENCIES

Institutional apprenticeships in the form of residencies in special fields of medicine, instituted at the Johns Hopkins Hospital in 1889, were but slowly adopted by other institutions. The first list of available residencies published by the Council nearly forty years later included the names of 278 hospitals and 1,776 residencies. In recent years, however, the number of institutions offering this type of service has increased with surprising rapidity. Currently there are 587 hospitals employing 5,118 physicians as residents in specialties. Two factors at least have contributed to this growth; namely, the creation of examining boards in the specialties which require of their candidates training and experience most readily secured in a hospital, and the more and more widespread recognition on the part of hospital staffs that the welfare of patients is enhanced by the presence in the hospital of house officers having greater maturity of judgment and a higher degree of technical skill than can be expected of interns less than one year out of medical school. Growing pains almost inevitably accompany such rapid development. There are not wanting indications that the residency is not yet fully adjusted to its surroundings. In the *New England Journal of Medicine* for June 20 an editorial comments on the financial and educational responsibilities assumed by the hospital embarking on a program of residency training. No doubt the cost for salaries and maintenance is compensated by the advantages which accrue to the hospital. The formulation and execution of a suitable educational program for residents makes demands by no means negligible on the time and energy of the attending staff. The hospital, however, should not assume obligations which it is unable to fulfil and must be content to make that contribution to graduate medical education which its resources, financial, clinical and personal, permit. The candidate who desires five years of training, let us say, in surgery need not necessarily spend the whole time in a single institution. Sometimes he may, with the utmost profit, migrate through several institutions each of which offers something of special value to him. In the appraisal of educational opportunities the time element should never be the sole criterion. It may even be the least important. The content of the program, the methods of instruction, professional standards and the personnel of the staff are the significant factors in evaluating a resident service.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

MEDICAL PREPAREDNESS IN PHILADELPHIA

A course for civilian physicians on "Medical Preparedness in the Present National Emergency" will be given by the Philadelphia County Medical Society at the Society Building, Twenty-First and Spruce streets.

The course will be sponsored also by the following participating organizations:

The Homeopathic Medical Society of the County of Philadelphia.

The Philadelphia County Dental Society.

The Keystone Veterinary Medical Association.

The W. W. Keen Chapter, Association of Military Surgeons of the United States.

It will be in charge of the Committee on National Defense of the Philadelphia County Medical Society and representatives from the other participating organizations.

The first meeting will be held September 10 at 9 p. m., when the following program will be presented:

"The Military Policy of the United States," by Major Russell B. Reynolds, Infantry, U. S. Army.

"The Doctor in the Army," by Lieut. Col. John M. Welch, Medical Corps, U. S. Army.

"The Doctor in the Navy," by Captain John B. Kauffman, Medical Corps, U. S. Navy.

The other meetings will be held weekly on Thursday afternoons from 4:30 to 6 o'clock, beginning September 19 and continuing for several months.

The program for the first afternoon meeting on September 19 will be as follows:

"The Selective Service Act and the Physician."

"The Contemplated Selective Service Act—Machinery and Operation," by Lieutenant Colonel Nicholas K. Biddle, Pennsylvania National Guard.

The following will be the program for the meeting on September 26:

"Noncombatant Military Hospitals and Medical Installations—Civilian Institution Sponsored Hospitals of the Army" (speaker to be announced).

VOLUNTEER SURGICAL UNIT GOES TO ENGLAND

A group of five orthopedic surgeons, a plastic surgeon and a general surgeon under the direction of Dr. Philip D. Wilson, chief surgeon of the Hospital for Ruptured and Crippled, New York, sailed for England August 22 to give their services to British war victims, the New York Times reports.

The group, which also included three surgical nurses, a medical artist and a secretary, is sponsored by the Allied Relief Fund, which is campaigning for medical and civilian relief for England. According to the Times, Dr. Wilson formed the American Hospital in Britain, Ltd., last May after hearing that American medical assistance would be welcomed. Members of this first unit have volunteered for six months' service,

an office will be maintained in New York for servicing the unit and selecting staff replacements. Sufficient equipment to enable the unit to operate independently of British aid for several months was placed aboard the ship.

In addition to Dr. Wilson, the unit included Drs. Donald E. Dial, Frederick William Waknitz, John M. Converse, all of New York; Charles Hickling Bradford, Boston; William Richard Ferguson, Baltimore, and Norman Egel, Rochester, N. Y.; Misses Miriam L. Knight, Adelbert Ethel Overman and Mildred Lillian Lewis, Mrs. Sheila M. Converse and Mrs. Helen Darcy Dial, New York.

TERRITORIAL COMMITTEE ON MEDICAL PREPAREDNESS

The Puerto Rico Medical Association appointed its Territorial Committee on Medical Preparedness to work in cooperation with the state representative of the Committee on Medical Preparedness of the American Medical Association.

The committee has already started to work in the selection of the members that are to make up the local boards, the advisory boards and the inspecting personnel to be employed in the examination of the indicted civilians when the conscription law is approved and goes into effect.

Major Luis de la Vega of the Medical Corps of the National Guard of Puerto Rico, who is in charge of this work, was appointed adviser ex officio of the committee, as his military duties today prevent him from accepting a position in the committee.

The following are members of the Territorial Committee:

Dr. O. Costa Mandry, chairman.
Dr. E. Garrido Morales, San Juan.
Dr. David García, Rio Piedras.
Dr. M. de la Pila Iglesias, Ponce.
Dr. M. Guzmán Rodríguez, Mayaguez.
Dr. Nestor de Cardona, Aguadilla.
Dr. Eduardo Pérez, Guayama.
Dr. Manuel Astor, Arecibo.
Dr. Cesar Domínguez, Humacao.

INVENTORY OF HEALTH RESOURCES FOR DEFENSE PREPARATION

The Temporary Legislative Commission to Formulate a Long Range Health Program held a conference in New York, July 30, with representatives of various agencies on availability of health resources in the state in relation to preparation for national defense. Among the subjects on which the commission sought information were the availability and number of buildings that can be used as hospitals, space and availability for emergency beds in existing hospitals, resources for the production of tetanus toxoid in quantity, availability of

medical schools for teaching public health personnel, methods for selection of specialists, availability of industrial hygienists, dentists and sanitary engineers, the status of present personnel as to membership in National Guard or Reserves, rehabilitation of the unemployed and the number and availability of nurses and physicians. General discussion ended in an expression of opinion that the recommendation might well be made to the government of the state for the setting up of local defense committees embracing the various organizations interested in health, including the medical, dental and pharmaceutical professions, according to a report in the *New York State Journal of Medicine*. The conference was called by Lieutenant Governor Poletti as coordinator for national defense for the state.

NEW YORK PREPARES

At the request of the committee on medical preparedness of the Medical Society of the State of New York, a conference was held in Albany, July 29, of secretaries or other representatives of all county medical societies in the state, officers of the state society and chairmen of the committees on public health and education, public relations and economics, and representatives of the public relations bureau and of the temporary legislative commission to formulate a state health program. Dr. Samuel J. Kopetzky, New York, chairman of the committee on medical preparedness, explained the framework of plans for cooperative work with the government in case of war conditions. Drs. Louis H. Bauer, Hempstead, and Edward T. Wentworth, Rochester, members of the committee, discussed questionnaires which the committee proposes to send out locally in addition to the national questionnaire distributed by the American Medical Association. Dr. O. W. H. Mitchell, chairman of the committee on public health and education, discussed plans for postgraduate instruction in subjects of particular importance in military medicine.

SURGICAL AID FOR THE BRITISH

Forty-eight physicians have formed the Medical and Surgical Supply Committee, with offices at 420 Lexington Avenue, New York, and undertaken a nationwide campaign for surgical and medical supplies to equip 500 first aid stations and field hospitals to aid in caring for the British war wounded. According to the *New York Times*, England has insufficient medical and surgical equipment to meet the present emergency. A first aid post, the committee said, can be equipped for \$500. Among those on the committee are Drs. Joseph Feisen, Conrad Berens and Franz Groedel. The executive chairman of the committee is Mrs. Ronald B. Balconi.

BLOOD TO AID THE BRITISH WOUNDED

The New York Red Cross Chapter has announced that more than 300 persons have volunteered to donate blood to aid in the treatment of British war wounded. The technical work of the project is being done by the Blood Transfusion Betterment Association, Plasma Division, 3 East 103d Street, New York City. Persons willing to donate blood should write or telephone the association, Sacramento 2-8950.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Plague Infection in Fleas.—Plague infection has been proved in a pool of thirty-eight fleas from twenty-one golden mantled ground squirrels submitted to the state department of health laboratory, June 26, from a location 1 mile north of Fawnskin Resort, San Bernardino County.

Graduate Study for Central American Physicians.—The University of California Medical School, San Francisco, has adopted a plan whereby two young graduate physicians who speak English will be sent every year by each of the Central American nations for two years' special study in pre-clinical and clinical subjects under the guidance of an advisory committee. The committee will consist of Drs. Howard C. Naffziger, professor of surgery; Charles L. Connor, professor of pathology, and Ralph Soto-Hall, clinical instructor in orthopedic surgery.

CONNECTICUT

Dr. Blumer Retires.—Dr. George Blumer, since 1920 David P. Smith clinical professor of medicine, Yale University School of Medicine, New Haven, was guest at a dinner in June to mark his retirement from active service at the school. Dr. Francis G. Blake was toastmaster. The speakers included Drs. Stanhope Bayne-Jones, Milton C. Winternitz, William F. Verdi, Fu-ching Yen, a former student of Dr. Blumer and minister of health of the republic of China, and James R. Angell, LL.D. Born in Darlington, England, in 1872, Dr. Blumer graduated at Cooper Medical College, San Francisco, which is now known as Stanford University School of Medicine, in 1891. After serving on the faculties of Albany Medical College, Albany, N. Y., Cooper, and the University of California Medical School, Dr. Blumer joined the staff at Yale as professor of the theory and practice of medicine in 1906, then was John Slade Ely professor of the theory and practice of medicine from 1908 to 1920. He was dean of the school from 1910 to 1920. He has served as president of the New Haven city and county medical associations and of the Connecticut State Medical Society. Dr. Blumer has written extensively on medical subjects and collects prints of medical men as a hobby. He has been a member of the House of Delegates of the American Medical Association for many years.

GEORGIA

Annual Clinical Conference.—The Georgia section of the Southeastern Surgical Congress will hold its annual clinical conference at Statesboro, September 11, at the Bulloch County Hospital. The speakers will include:

- Dr. Alfonso John Mooney Jr., Statesboro, Nephrolithiasis (A Sectional Problem).
- Dr. James H. Whiteside, Statesboro, Ruptured Duodenal Ulcer.
- Dr. Rufus L. Cone, Statesboro, Neurosurgery.
- Dr. Patrick H. Smith, Savannah, Compound Fractures with Gas Bacillus Infection.
- Dr. Job C. Patterson, Cuthbert, Educational Value of Rural Meetings of the Southeastern Surgical Congress.
- Dr. Alfonso J. Mooney Sr., Statesboro, Carcinoma of the Uterus.
- Dr. Robert Louis Kennedy, Metter, Cesarean Section.
- Dr. Abram Bird Daniel, Statesboro, Acute Appendicitis with Drainage.
- Dr. Cleveland Thompson, Millen, The Role of the Liver in Surgical Patients.

The speakers at the luncheon will include Dave Turner, editor of the *Bulloch Times*, Dr. Benjamin T. Beasley, Atlanta, secretary-treasurer of the Southeastern Surgical Congress, and Dr. Allen H. Bunce, Atlanta, president-elect, Medical Association of Georgia.

IDAHO

State Medical Meeting at Sun Valley.—The forty-eighth annual meeting of the Idaho State Medical Association will be held at Sun Valley, September 11-14, under the presidency of Dr. Fern M. Cole, Caldwell. A new feature of the program will be instruction courses each morning before the formal program by guest speakers. The lecturers will be:

- Dr. Abram M. Newton, Pocatello, Treatment of Fractures of the Shaft of the Femur.
- Dr. Arthur C. Jones, Boise, Commoner Diseases of the Eye, Ear, Nose and Throat.

Dr. Frank C. Gibson, Potlatch, Traumatic and Industrial Surgery.
Dr. Harry Alban, Kimberly, Acute Anterior Poliomyelitis.
Dr. James O. Cromwell, Blackfoot, The Neuroses.
Dr. Harold E. Dedman, Boise, Endometriosis, Diagnosis and Management.

The guest speakers, all of the State University of Iowa College of Medicine, Iowa City, who will give several addresses each, will be:

Dr. Ewen M. MacEwen, dean and professor of anatomy.
Dr. Adolph L. Sals, assistant professor of neurology.
Dr. Fred M. Smith, professor of theory and practice of medicine.
Dr. Nathaniel G. Alcock, professor of urology.
Dr. Arthur Steindler, professor of orthopedic surgery.

MAINE

Society News.—At a joint meeting of Aroostook, Kennebec, Penobscot, Piscataquis and Somerset county medical societies in Greenville, July 25, Dr. John Homans, Boston, spoke on the following subjects in a surgical panel discussion: head injuries, acute intestinal obstruction, peripheral arterial gangrene and emphyema. Dr. William B. S. Thomas, Dover-Foxcroft, discussed "The Cause of Some Diseases of Unknown Etiology."—Dr. Charles B. Sylvester, Portland, was elected president of the Maine Public Health Association at its twenty-ninth annual meeting in Kennebunk, July 11.—Frauz U. Burkett, Portland, was chosen president of the Maine Medical-Legal Society at its annual meeting in Rangeley, June 25; Dr. William Holt, Portland, vice president; George L. Pratt, Farmington, secretary, and Walter S. Stinchfield, Skowhegan, treasurer.

MICHIGAN

Society News.—Dr. Richard A. Burke, Palmer, was chosen president-elect of the Upper Peninsula Medical Society at its annual meeting, July 10, and Dr. William Ellwood Tew, Bessemer, was installed as president.—Dr. Victor G. Heiser, New York, discussed "Health in Industry" before the Muskegon County Medical Society, Muskegon, recently.

Personal.—Dr. Robert J. Schneck has been appointed to the public welfare commission of Detroit, succeeding Dr. Frederick H. Cole. Dr. Schneck's appointment is for a four year term ending March 1, 1944.—Edward D. Rich, C.E., associated with the state department of health for twenty-nine years and for twenty-seven years director of the bureau of engineering, has retired, effective July 1. He has been succeeded by John M. Hepler, C.E., associate director, who has been connected with the department since 1919.—Dr. John Alexander, Ann Arbor, received the honorary degree of doctor of science from the University of Pennsylvania, Philadelphia, at the June commencement.

NEBRASKA

Course in Obstetrics and Pediatrics.—A two weeks course in obstetrics and pediatrics will be presented in five towns in western Nebraska, September 9-20, by the division of maternal and child health, Nebraska State Department of Health, in cooperation with the maternal and child health committee of the Nebraska State Medical Association and the University of Nebraska School of Medicine. Drs. Willis E. Brown, assistant professor of obstetrics and gynecology, and John L. Gedgoud, assistant professor of pediatrics at the university, will be the instructors. They will conduct clinics in the afternoons and lecture in the evenings. They will make a circuit each week of the following towns: Alliance, Chadron, Scottsbluff, North Platte and McCook.

NEW JERSEY

Personal.—Dr. Wells P. Eagleton, Newark, retired from the board of trustees of the Medical Society of New Jersey at the recent annual meeting after having served continuously for twenty-one years. The society presented to Dr. Eagleton its award of merit in recognition of "his services as medical director of the Newark Eye and Ear Infirmary for thirty years; for his ability as a brain surgeon; for his contributions to the literature on diseases and surgery of the brain; for the origination and development of many surgical procedures in the field of brain surgery, all of which have contributed to the advancement of scientific medicine in New Jersey and the nation."—Dr. William Russell Greenwood, assistant physician at Rutgers University, New Brunswick, has been appointed university physician and head of the department of student health, it is reported. He succeeds Dr. Joseph H. Kler, who resigned to devote more time to his private practice, but will remain as associate head of the department.

NEW YORK

Report on Typhoid Carriers.—The New York State Department of Health reports that 422 typhoid carriers were under its supervision in upstate New York at the close of 1939. Thirty-six new carriers were added to the list and twenty-six were removed during the year. Twenty-five were discovered as a result of investigation of sporadic cases of typhoid and eight by means of release cultures. Three were added on evidence submitted by other state health departments. Sixteen of those removed died; five were released after cholecystectomy and the required tests and five changed their place of residence.

Annual Chautauqua Meeting.—The ninth annual meeting of the Interstate Medical Association was held in Chautauqua, July 24. Dr. Nathan B. Van Etten, New York, President of the American Medical Association, gave an address; other speakers were Drs. Russell L. Haden, Cleveland, on "The Care of Anemia"; Arthur G. Davis, Erie, Pa., "The Care of Compound Wounds," and Abraham H. Aaron, Buffalo, "Self Medication and Its Dangers." There was also a panel discussion on "Recent Advances in Therapeutics" by Drs. Aaron, Louis Maxwell Lockie, Clayton W. Greene, Francis D. Leopold and Frank Meyers, all of Buffalo.

Society News.—Dr. William J. Hoffman, New York, addressed the Greene County Medical Society, Haines Falls, July 9, on "Modern Treatment of Cancer."—Drs. Samuel Edward Navarra and Milton Sills Lloyd, New York, addressed the Richmond County Medical Society in June on "Management of Strabismus" and "Pathology of Bullous Emphysema" respectively.—The Medical Society of the County of Schenectady has recently organized an orchestra, which gave its first concert at the recent semiannual meeting of the society after four months of rehearsal.—Dr. Leon M. Kysor, Hornell, was elected president of the Lake Keuka Medical and Surgical Association at the recent annual meeting at Penn Yan. Dr. Noble R. Chambers, Syracuse, was elected vice president and Dr. Virgil H. F. Boeck, Dundee, reelected secretary.

New York City

Graduate Courses at New York University.—Graduate courses are now being given in nine fields at New York University College of Medicine, it is announced. The period of study varies from one to three years and may be taken as preparatory training for a residency or complete training for specialty board examinations. Information about this type of work may be obtained from the office of the dean, 477 First Avenue, New York.

Lectures on Venereal Disease.—The bureau of social hygiene of the New York City Department of Health announces two groups of lectures on "Ambulatory Treatment of Venereal Diseases" to be held on Saturday mornings in the fall. The schedule follows:

September 14, Nonsyphilitic Infectious Granulomas.
September 21, Acute Gonorrhea in the Male.
September 28, Postacute Gonorrhea in the Male.
October 19, Infectious Syphilis, Primary.
October 26, Infectious Syphilis, Secondary.
November 2, Venereal Disease Control Measures.

The New York State Department of Health and the U. S. Public Health Service are cooperating in this program as part of the national defense preparedness program.

Medical War Relief Committee.—The American Doctors' War Relief Committee has been formed for neutral, non-military aid to the sick and wounded in Europe. Officers are Dr. Clarence R. Straatsma chairman, Drs. Thomas H. Russell and Walter D. Ludlum Jr. vice chairmen, Dr. E. Forrest Merrill, executive secretary, and Dr. Con Amore V. Burt, treasurer. The committee is arranging to send mobile clinics, consisting of a trailer equipped for emergency operations and two light trucks to carry supplies. Physicians and surgeons to accompany each clinic will be chosen from American volunteers and native nurses will assist them. Each unit will, if possible, serve a circuit of seven towns and villages, devoting one day a week to each. The committee has headquarters at 18 Gramercy Park, with Mr. C. J. B. Harris as corresponding secretary.

NORTH CAROLINA

University News.—The division of public health at the University of North Carolina, Chapel Hill, has been changed to the School of Public Health, with Dr. Milton J. Rosenau as the dean. Dr. Rosenau has been director of the division of public health since it was established in 1936.

New Health Officers.—Dr. Margery J. Lord, Asheville, has been appointed city health officer, effective after she has completed a qualifying course in public health at the University of North Carolina. She has been acting health officer since December 1939. —Dr. James J. Croley, McKinney, Texas, has been appointed health officer of Avery and Yancey counties to succeed Dr. Roderic O. Jones, who has entered private practice in Burnsville. —Dr. Harold C. Whims, Rutherfordton, has resigned as health officer of the Rutherford-Polk counties health unit to take a similar position in the Catawba-Lincoln counties district.

OHIO

Commissioner of Mental Diseases Appointed.—Dr. Roy E. Bushong, superintendent of the Cleveland State Hospital, Cleveland, has been appointed state commissioner of mental diseases. He will collaborate with the department of public welfare in the supervision of the state institutions for the mentally ill, feeble-minded and epileptic. Dr. Bushong succeeds Dr. Jesse Fremont Bateman, Columbus, who resigned to return to his former post as superintendent of the Columbus State Hospital.

PENNSYLVANIA

District Meeting.—The Fifth Councilor District of the Medical Society of the State of Pennsylvania held its annual meeting in York, August 22. Among the speakers were Drs. Charles-Francis Long, Philadelphia, on "Industrial Medicine—A Pressing Problem for All Physicians"; Harvey F. Smith, Harrisburg, "Preventable Deaths Among Youth Groups," and John J. Shaw, state secretary of health, Harrisburg, "Private Practitioner, Keystone of the Public Health Arch." The following officers of the state medical society also made addresses: Drs. Francis F. Borzell, Philadelphia, president-elect; Charles H. Henninger, Pittsburgh, president; Walter F. Donaldson, Pittsburgh, secretary, and Chauncey L. Palmer, Pittsburgh, chairman of the committee on public health legislation.

Philadelphia

Grants for Cancer Research.—The International Cancer Research Foundation has voted a grant of \$1,200 to the Woman's Medical College of Pennsylvania for the use of Dr. Catharine Macfarlane in her studies of cancer of the uterus. The Pennsylvania division of the Woman's Field Army of the American Society for the Control of Cancer has contributed \$250 to the same research.

Dr. Scheffey Succeeds Dr. Anspach.—Dr. Lewis C. Scheffey, clinical professor of gynecology, Jefferson Medical College of Philadelphia, has been elected professor of gynecology to succeed Dr. Brooke M. Anspach, who became professor emeritus. Dr. Scheffey graduated from Jefferson in 1920 and had previously taken a degree in pharmacy from the Philadelphia College of Pharmacy and Science. He served as resident physician in Jefferson Hospital from 1920 to 1922 and has been associated with the department of gynecology since that time. Dr. Anspach has held the chair of gynecology at Jefferson since 1921 and has been on the faculty since 1917.

Retirements at Temple.—Dr. Frank C. Hammond, professor of gynecology at Temple University School of Medicine since 1923 and dean from 1906 to 1929, and Dr. Jesse O. Arnold, professor of obstetrics, have resigned. Dr. Hammond, who is also editor of the *Pennsylvania Medical Journal*, will continue as chairman of the medical faculty. Dr. Arnold will be professor emeritus and senior obstetric consultant. Dr. Thaddeus L. Montgomery, clinical professor of obstetrics at Jefferson Medical College of Philadelphia, has been appointed head of the department of obstetrics and gynecology, succeeding both Dr. Hammond and Dr. Arnold. Dr. Montgomery graduated from Jefferson in 1920.

TENNESSEE

Changes in Health Officers.—Dr. John H. Solomon, Nashville, has been appointed health officer of a new health unit in Marshall County, with headquarters at Lewisburg. —Dr. Harry H. Hudson, Dyersburg, has succeeded Dr. Albert L. Ball, Cleveland, as head of the Bradley County health unit.

Society News.—Dr. Edward T. Newell addressed the Chattanooga and Hamilton County Medical Society, August 1, on "Cancer of the Breast: Cautey Excision Supported by Radium and X-Ray." —Dr. Robert H. Elder, Cedar Hill, discussed "Infant Diarrheas" at a meeting of the Robertson County Medical Society, Springfield, July 16.

VIRGINIA

State Medical Election.—The Medical Society of Virginia chose Dr. Roshier W. Miller, Richmond, as president-elect at its annual meeting at White Sulphur Springs, W. Va., in a joint session with the West Virginia Medical Association. Dr. Walter B. Martin, Norfolk, will become president in October. Vice presidents elected were Drs. John M. Emmett, Clifton Forge; John E. Knight, Warrenton, and Henry B. Mulholland, Charlottesville. The 1941 meeting will be held at Virginia Beach.

WASHINGTON

Dr. Sharples Honored.—A reception and dinner honoring Dr. Caspar W. Sharples, Seattle, on his completion of fifty years of practice was given by the King County Medical Society and the Washington State Medical Association at the Olympic Hotel, Seattle, July 13. About 300 attended. Dr. Sharples graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1888 and was licensed in 1890. He is chief of staff of the Children's Orthopedic Hospital and medical superintendent of the Seattle General Hospital. He is a past president of the North Pacific Surgical Association.

WEST VIRGINIA

Changes in Health Officers.—Dr. Edward G. McGavran, formerly with the Kellogg Foundation at Hillsdale, Mich., has been appointed health officer of Monongalia County to succeed Dr. Edwin Cameron, Morgantown, who became secretary of the Delaware State Board of Health. —Dr. William W. Hume, Beckley, has resigned as health officer of Raleigh County because of ill health. Dr. James M. Coram, St. Marys, is acting health officer.

Outbreak of Poliomyelitis.—More than 100 cases of poliomyelitis were reported in several counties in southern West Virginia, August 17. Thirty-nine cases, the largest number, with three deaths were reported in Cabell County. Logan County was second with twenty cases. One death each had been reported in Fayette and Kanawha counties. The West Virginia State Medical Association and the state department of public assistance are cooperating with the state department of public health in plans for prevention and rehabilitation. Restrictions against gatherings of children have been in force for several weeks in Huntington, where the disease first made its appearance, it was said.

WISCONSIN

State Medical Meeting in Milwaukee.—The program of the ninety-ninth annual meeting of the State Medical Society of Wisconsin to be held in Milwaukee, September 18-20, will place emphasis on industrial medicine and medicomilitary affairs. Twenty-five speakers from outside the state will appear at general and sectional meetings and at round table luncheons. The list includes:

- Dr. Anthony J. Lanza, New York, Silicosis with Special Reference to Wisconsin Industry.
- Dr. Gordon B. New, Rochester, Minn., Early and Late Treatment of Traumatic Injuries of the Face.
- Dr. Lee Foshay, Cincinnati, The Diagnosis of Brucellosis.
- Dr. Edwin F. Daily, Washington, D. C., Maternal Care and Maternal Mortality.
- Dr. Kellogg Speed, Chicago, Some Common Every Day Injuries Around the Knee Joint.
- Dr. Peter C. Kronfeld, Chicago, The Practical Value of Gonioscopy for the Understanding, Diagnosis and Treatment of Glaucoma.
- Dr. Walter M. Boothby, Rochester, Minn., Physiologic Problems Involved in Aviation.
- Col. Fred T. Cruise, F.A., U. S. Army, a medicomilitary subject.
- Brig. Gen. Ralph M. Immell, adjutant general of Wisconsin, a medicomilitary subject.
- Dr. John A. Bigler, Highland Park, Ill., Treatment of Pneumonia in Children with Sulfapyridine.

Dr. Franklin G. Ebaugh, professor of psychiatry, University of Colorado School of Medicine, Denver, will deliver the Rogers Memorial Lecture Thursday afternoon, September 19, on "Our Mental Health." At the annual dinner at the Hotel Schroeder Thursday evening the speaker will be Dr. Eben J. Carey, Milwaukee.

PUERTO RICO

University News.—Dr. Robert A. Lambert, associate director for the medical sciences, Rockefeller Foundation, New York, was guest of honor at a dinner in San Juan, July 14, given by physicians and former associates at the School of Tropical Medicine, University of Puerto Rico. Dr. Lambert was professor of pathology and the first director of the school, serving from 1926 to 1928.

GENERAL

New Organization of Surgeons.—During the recent annual meeting of the American Surgical Association in St. Louis, a new organization designed for the closer association of younger surgeons of the Middle West and the adjacent Canadian provinces was formed, to be known as the Central Surgical Association. Officers elected were Drs. Roy D. McClure, Detroit, president; Grover C. Penberthy, Detroit, president-elect, and George M. Curtis, Columbus, Ohio, secretary. The first regular meeting will be held in February 1941 at the University Hospital, Ann Arbor, Mich.

Funds for Venereal Disease Control.—The U. S. Public Health Service has allotted \$5,672,388 to the states and territories and the District of Columbia for venereal disease control during the coming year. A special portion of these grants, amounting to \$458,600, has been allotted on the basis of the extent of military and national defense industrial concentrations, it was announced. The remainder will be used to further research in new methods of treatment and diagnosis of syphilis and gonorrhea, for training of personnel, for coordination of educational efforts, and for cooperation with the states in planning and administration of the control program.

Association for Study of Neoplastic Diseases.—The annual meeting of the American Association for the Study of Neoplastic Diseases will be held at the Mayflower Hotel, Washington, D. C., September 5-7. Among speakers announced on the program are:

- Dr. William T. McClure, Wheeling, W. Va., Adenocarcinoma of Ducts Engraffed on Old Cystic Disease.
- Dr. Wright Clarkson, Petersburg, Va., Chronic Cystic Mastitis in the Male.
- Dr. Charles F. Geschickter, Baltimore, Mammary, Gynecologic and Other Forms of Cancer in Rats Treated with Estrogens.
- Dr. Rollin H. Stevens, Detroit, Present Day Treatment of Neoplasia and What Experimental Biochemistry Suggests for the Future.
- Dr. Edgar C. Baker, Youngstown, Ohio, Three Cases of Bone Lesions Causing Paralysis of Lower Extremities.
- Dr. Russell S. Ferguson, New York, Teratoma Testis.
- Dr. Oscar B. Hunter, Washington, D. C., Tumor of the Thyroid Gland.
- Drs. Louis Wallace Frank and Aura J. Miller, Louisville, Ky., Epithelioma of the Labia, with Discussion of Methods of Treatment.
- Dr. Edwin A. Merritt, Washington, D. C., The Revised Clinical Classification of Carcinoma of the Cervix.
- Dr. Louisa E. Keasbey, Lancaster, Pa., Primary Carcinoma of the Fallopian Tube.

Inter-American Society of Microbiology.—Committees have been appointed in fourteen South and Central American countries and in Cuba for the formation of an Inter-American Society of Microbiology, the initial plans for which were made at the close of the meeting of the International Congress of Microbiology in New York in September 1939 (THE JOURNAL, Dec. 23, 1939, p. 2332). The first congress of the new society is scheduled to take place in Brazil, with Dr. Antonio Fontes, director of the Instituto Oswaldo Cruz, Rio de Janeiro, as president. Dr. Francesc Duran-Reynals, research assistant in bacteriology, Yale University School of Medicine, New Haven, Conn., executive secretary, points out that steps that remain to be taken include organization of branches in the United States and Canada, establishment of a relationship with the International Society of Microbiology and establishment in the United States of an inter-American journal of microbiology, to be published in English and open to contributors from all American countries.

Changes in Status of Licensure.—The Alabama State Board of Medical Examiners reports the following:

Dr. Abijah Clements Fields, Birmingham, license restored, April 15.

The Illinois Department of Registration in Medicine announces the following:

Dr. James W. Ross, Harrisburg, Ill., license revoked, June 15, for violation of the Harrison Narcotic Act.

Dr. George Walton Gore, Benton, license revoked, April 20, for conviction of murder.

The Massachusetts Board of Registration in Medicine announces the following action:

Dr. Herbert N. du Gerardell, East Boston, license revoked, April 18, for gross misconduct in the practice of his profession as shown by deceit.

The Michigan State Board of Registration in Medicine announces the following action:

Dr. Boyajian Bedros Armen, Fresno, Calif., license revoked, June 11, for violation of the narcotic laws of California.

The New York State Board of Medical Examiners reports the following:

Dr. Saverio Bonta, New York, license revoked, June 20, on the basis of his having been convicted of a felony.

Dr. Charles I. Gordon, formerly of Brooklyn, license reinstated; it was revoked June 16, 1939.

American Hospital Association.—The forty-second annual convention of the American Hospital Association will be held at the Hotel Statler, Boston, September 16-20, under the presidency of Dr. Fred G. Carter, Cleveland. A feature of the meeting will be a general session on preparedness with addresses by the surgeons general of the Army, Navy and Public Health Service. Among addresses to be given in section meetings will be the following:

- Dr. Sigismund S. Goldwater, New York, Next Steps in Hospital Service Plans.
- Dr. Thomas T. Mackie and Dorothy DeHart, M.A., New York, A Nutritional Study of Hospital Diets.
- Drs. Herman E. Hilleboe, St. Paul, and Maxim Pollak, Peoria, Ill., The Tuberculosis Problem in Mental Hospitals.
- Dr. Charles F. Wilinsky, Boston, What Is Hospital Indigency?
- Dr. Stanley J. Seeger, Milwaukee, The Content and Management of a Program of Education of Interns and Residents in a Small Hospital.

A symposium on "The Role of the General Hospital in the Control of Tuberculosis" will be presented by the following: Mr. John Hayes, superintendent of Lenox Hill Hospital, New York; Drs. Theodore L. Badger, Boston; Richard H. Overholt, Brookline, Mass.; Monroe J. Tanner, Ridgewood, N. J.; Alice L. Spellman and Katharine G. Amberson, both of Albany Hospital, Albany, N. Y. The annual banquet will be held Thursday evening, September 19, when Dr. Benjamin W. Black, Oakland, Calif., will be installed as president. Other organizations which will meet at the same time include: American Protestant Hospital Association, American Association of Nurse Anesthetists, American Association of Occupational Therapists and American College of Hospital Administrators.

Bequests and Donations.—The following bequests and donations have been announced in recent months:

- Mount Sinai Hospital, \$50,000, and Beckman Street Hospital, \$5,000, by the will of the late Joseph F. Cullman. Both are in New York.
- Lawrence Hospital, Bronxville, New Rochelle Hospital, New Rochelle, N. Y., and Mount Vernon Hospital, Mount Vernon, N. Y., \$1,000 each by the will of the late George L. Bourne, Larchmont.
- French Hospital, New York, \$25,000, and St. Francis Sanatorium for Cardiac Children, Flower Hill, Roslyn, L. I., \$50,000 by the will of the late Carlos W. Munson.
- Touro Infirmary, New Orleans, \$250,000 from Mrs. Norman C. Mayer in memory of her husband.
- French Hospital, New York, \$50,000 by the will of Albert Blum.
- University Hospital, Philadelphia, \$2,500; National Jewish Hospital, Denver, \$2,000, and Jewish Hospital Association, Philadelphia, \$1,000 by the will of Mrs. Anna E. Fridenberg.
- Philadelphia Orthopedic Hospital, \$20,000; Children's Hospital, \$30,000, and Pennsylvania Institute for Instruction of the Blind, \$30,000 by the will of the late Mrs. Josephine Eisenlohr.
- Brady Urological Institute, Johns Hopkins University, Baltimore, \$10,000 by the will of the late Willis Sharpe Kilmer, Binghamton, N. Y.
- Episcopal Hospital of Philadelphia, the residuary estate of Margaret G. Holson, amounting to about \$45,000, after the death of trust fund beneficiaries.
- Jewish Hospital, Philadelphia, approximately \$250,000 to build the Mary and David Hirsch Memorial Home for student nurses at the hospital, by the will of Mrs. Hirsch.
- Germantown Hospital, Germantown, Pa., \$5,000, and Northern Liberties Hospital, Philadelphia, \$1,000 from the estate of the late Liborio Delino.
- Lankenau Hospital, Philadelphia, \$5,000 by the will of Anna Lindhorst.
- Misericordia Hospital and Babies' Hospital, Philadelphia, \$5,000 each by the will of Michael J. Smith.
- Wistar Institute of Anatomy, Philadelphia, about \$13,000 to establish a fund to pay salaries of investigators. The fund was left by Mrs. Frances Hancock Greenman in memory of her husband, the late Dr. Milton J. Greenman, director of the institute for many years.
- Reading Hospital, Reading, Pa., \$10,000, and Crozer Home and Hospital, Chester, \$5,000 by the will of Alvin B. Ebst.
- St. Luke's Hospital and Manhattan Eye, Ear and Throat Hospital, New York, \$10,000 each by the will of the late Mrs. Richard Marsh Hoe.
- Presbyterian Hospital, New York, \$5,000 by the will of Mrs. Lila V. Field.
- New York Skin and Cancer unit of the New York Postgraduate Medical School and Hospital, \$6,000 by the will of Mrs. Miriam L. Mooney.

CANADA

Canadian Society Elections.—Dr. Gordon S. Fahrni, Winnipeg, was chosen president-elect of the Canadian Medical Association at the annual meeting in Toronto in June, and Dr. Duncan Graham, Toronto, became president.—Dr. John H. Holbrook, Hamilton, Ont., was chosen president-elect of the Canadian Tuberculosis Association at the annual meeting in Montreal in June and Dr. J. Arthur Jarry, Montreal, became president. Dr. Robert E. Wodehouse, Ottawa, was elected vice president.

British Columbia Meeting.—The annual meeting of the British Columbia Medical Association will be held in Nelson, B. C., September 9-11. Among the speakers will be Drs. Albert M. Snell, Rochester, Minn., who will speak on "Deficiency States and Their Treatment" and "Problems Presented by the Jaundiced Patient"; Stuart W. Harrington, Rochester, "Diagnosis and Results of Radical Mastectomy for Carcinoma of the Breast in 5,026 Cases" and "Differential Diagnosis of

Diaphragmatic Hernia from Other Abdominal and Intra-thoracic Conditions and Surgical Treatment in 250 Cases" and George H. Anderson, Spokane, "Hyperventilation Syndrome."

Canadian Physicians to Care for Children of British Physicians.—The Canadian Medical Association has informed the British Medical Association that homes of physicians in several provinces are ready to receive more than 1,100 children of British physicians, according to an announcement in the *Canadian Medical Association Journal*. Dr. Thomas C. Routley, Toronto, general secretary of the Canadian association, in a letter sent to secretaries of all divisions explained the plans agreed on by the Dominion and Provincial governments. He suggested that the secretaries ascertain the wishes of the medical profession with regard to the acceptance of children; notify the proper provincial authorities of the homes offered or advise doctors offering homes to notify the local welfare office; advise the doctors offering their homes that all further negotiations leading to the placing of children will be carried on between the governmental agency and the doctor. He also suggested that the divisions organize committees which would be responsible for taking a corporate interest in the children. Among other points in the plan Dr. Routley pointed out that hosts will be expected to provide maintenance and all other costs of these children in a manner similar to the care they would give their own children, except that the Dominion government will be responsible under certain conditions. The host will, for instance, be expected to provide ordinary medical care, but under no circumstances will the host be called on to bear the cost of hospitalization or major medical care, the department of public welfare for Ontario announced.

LATIN AMERICA

Society News.—The first National Congress of Child Welfare (Congreso Nacional de Puericultura) will be held in Buenos Aires, Argentina, October 7-11. Subjects to be discussed include growth and physical development, psychic development, rickets, legislation and organization for prophylactic care of the child, prophylaxis of tuberculosis and indications of syphilis in childhood.

Personal.—Prof. W. H. Hoffmann of the Finlay Institute, Habana, Cuba, has been elected honorary member of the Sociedad Colombiana de Leprologia in Bogotá.—Dr. Clemente Estable, honorary professor of medicine in the National University of Uruguay and chief of the technical laboratory of histologic research in the National Neurologic Institute, Montevideo, is visiting laboratories and medical schools in the United States.—Prof. Octavio do Rego Lopes has been appointed in charge of clinical ophthalmology at the National Faculty of Medicine of the University of Brazil.—Dr. Ramon Castroviejo, New York, recently gave several lectures on ophthalmic surgery as the guest of the Daniel A. Carrión Peruvian Medical Association, Lima, Peru. The Faculty of Medical Sciences gave him an honorary degree and the medical association honored him at a banquet before his departure.

Deaths in Other Countries

Dr. William Russell, emeritus professor of clinical medicine, Edinburgh University, died August 12, aged 89. He was former president of the Royal College of Physicians, was the first editor of the *Scottish Medical and Surgical Journal* and wrote several books dealing principally with diseases of the heart and circulation.—Dr. Thierry de Martel, chief surgeon of the American Hospital of Paris, committed suicide on the day that the German Army occupied Paris.

Government Services

Personals

Dr. Edward J. Stieglitz, Garrett Park, Md., has been appointed research associate in gerontology at the National Institute of Health to organize a new unit of research to deal with problems of aging.

Capt. Robert E. Hoyt has succeeded Capt. Edgar L. Woods as commander of the Naval Hospital, Washington, D. C. Captain Hoyt was formerly medical officer in charge of the Naval Dispensary at Washington.

Dr. Hermon E. Hasseltine, Medical Director in the U. S. Public Health Service, has been transferred from the National Leprosarium at Carville, La., to Cincinnati as officer in charge of the stream pollution laboratory. Dr. Guy H. Faget, recently stationed in San Francisco, replaced Dr. Hasseltine as medical officer in charge at the Leprosarium.

The Food Situation

The food situation continues to be good but with the continuance of the war there are further restrictions. Margarine is now rationed as well as butter, and tea is rationed to 2 ounces a week per person. To spare shipping wanted for munitions the campaign to grow more food was started at the outbreak of the war and we have now two million more acres under cultivation. There is plenty of scope for more home grown food, for we are the only nation of which it can be said that normally we produce only 40 per cent of our total food. But our real production is not more than 30 per cent, because part of our home produced animal food is transformed into imported feeding stuffs. It is realized that we may have to go much further in relying on home produced food. In the House of Commons Mr. Hudson, minister of agriculture, stated that we must take steps to raise, as far as was possible, enough food to keep our population alive and in good health, even if our present imports should be seriously imperiled. Scientists stated that our people could exist in a state of health, do hard work, produce munitions and fight on a diet far different from that to which we were accustomed. The greater proportion of this diet could be grown in the country, so that, if necessary, we could manage with greatly reduced imports. He did not know that it would seem a very palatable diet, but the house would perhaps be relieved to know that he had put in a plea that it should be supplemented by beer. The Ministry of Food would lay down what food was to be produced. In many cases farmers would be asked to alter drastically their normal production.

A committee of eminent scientists has been appointed by the government to work out a basic plan of war time food policy. The chairman is Sir William Bragg, president of the Royal Society (physicist). Members of the committee include Prof. E. P. Cathcart, F.R.S. (physiologist), Sir John Boyd Orr, F.R.S., Prof. F. L. Engledow, F.R.S., Prof. A. W. Ashby and Prof. J. A. Scott-Watson (agriculturists) and Sir Edward Mellanby, F.R.S., secretary of the Medical Research Council (biochemist). The committee will work out a basic plan of war time food policy for the country.

Stored Blood for Transfusion

From the Emergency Blood Transfusion Service of Edinburgh and Southeast Scotland C. P. Stewart reports in the *Edinburgh Medical Journal* studies on the use of stored blood in 427 transfusions. He points out that for certain purposes the therapeutic value of blood must steadily decrease during storage. Thus the disappearance of leukocytes, reported by several observers, means that blood should not have been more than two days in store if one of the objects for which it is used is to supply leukocytes. But if the object is to supply fluid and oxygen carrying power there seems no reason, on the basis of laboratory examinations of stored blood, why it should not be used after as much as thirty days of storage. However, clinical trial is essential and it is extremely difficult to judge the relative value of stored and fresh blood. In surgical cases the therapeutic results appear to be independent of the age of the blood. But in such conditions as leukemia, various types of anemia, septicemia and toxemia, blood is now used which has been in store as short a time as possible and the results have greatly improved.

All the transfusions in this series were done with blood which had been withdrawn into 3.8 per cent sodium citrate solution with a final concentration of 0.38 per cent citrate, stored at a temperature of from 2 to 5 C. In most cases it had been filtered

after being stored for forty-eight hours. In the 427 cases there were fifty-eight reactions, of which nine were fatal; sixteen were only febrile, seven were transient jaundice and twenty-six were rigors. The total percentage of reactions was 13.6, which in the 259 cases of the series of transfusions done in the present year was reduced to 10.4 with only one death. This reduction of incidence of reactions coincided with the use of blood of lower average "age." The deaths appeared to be due to acute cardiac failure following injection of fluid and not to any factors which could be attributed to the use of stored blood, though some followed a transfusion reaction (rigor). One writer, V. H. Riddell, states in his book on Blood Transfusion that deaths from circulatory failure after transfusion with fresh blood are much commoner than is generally supposed, although they are rarely reported.

Stewart investigated the relation between the incidence of reactions and the time of storage by classifying the cases into five day periods. Under twenty-four hours the percentage was 12.5, from one to five days 14, from six to ten days 5.2, from eleven to fifteen days 15.6, from sixteen to twenty days 22, from twenty-one to twenty-five days 15 and from twenty-five to thirty days 26. When the cases were further analyzed according to the storage time in days from none to fourteen it was found that blood stored from four to ten days was safer than blood stored for a shorter time and even than fresh blood. The reason for this was not clear, but it might be related to the disappearance of leukocytes during the first few days of storage. The increased reaction incidence after the tenth day may be associated with the disruption of erythrocytes. It appears that stored blood is no more likely to produce reactions during the first fortnight than is fresh blood. But after that period the likelihood of reaction is increased. Therefore, while it is possible to use in cases of emergency blood stored longer than a fortnight, it seems better in ordinary cases to regard this period as the maximum.

SWITZERLAND

July 14, 1940.

Injuries in Airplane Crashes

Dr. Wegelin, professor of pathologic anatomy, recently discussed before the medical association of Berne the injuries sustained by fliers who crash to the ground. The injuries, he said, are exceedingly serious. Countless bone fractures, extensive lacerations of the soft parts, bruises and wounds in the abdominal region can be observed. Owing to the sudden increase in intra-abdominal pressure the viscera are everted into the thorax cavity with rupture of the diaphragm. Rupture of the scrotum is also observed. The sudden increase of intracardial pressure produces lesions in the region of the heart. The heart is often torn from the large vessels. Cardiac lesions, the speaker said, cause immediate cessation of the circulation. For that reason fat embolism is never observed. According to the literature, hemosiderin is discoverable in the lungs after hemorrhages that occur at high altitudes. This, however, has not been observed in aviators who crash. Wegelin was able to observe a heart that had burst at the apex.

Control of Mental Diseases

In proportion to its population, Switzerland has more institutions for the mentally diseased than any other European country, namely thirty-eight psychiatric beds per 10,000 inhabitants. Every public institution of this kind is provided, on the average, with 500 beds; private institutions have fewer than 100. The majority of mentally diseased patients remain hospitalized a relatively short time. In 1935 half of the inmates were confined for less than three months, 80 per cent for less than one year. Fifteen per cent of the patients were regarded as medically or at least socially cured, 45 per cent as improved

and 25 per cent in statu quo; 15 per cent died. The public cost for the care of the mentally diseased amounts to 20 million Swiss francs (about \$4,500,000) annually. Prophylaxis and control outside institutional care include welfare work, neuropsychiatric polyclinics, psychiatric observation stations for children, medicopedagogic arrangements and antialcohol welfare stations. All these agencies were supplemented by the creation about ten years ago of the Swiss national committee for mental hygiene, which deals with all problems connected with the control of mental diseases.

Swiss Society for Gastro-Enterology

The Schweizerische Gesellschaft für Gastro-Enterologie was organized a few years ago and recently held its annual meeting in Basel. The papers dealt with albuminous nutrition for sportsmen, esophagoplasty, effect of corticosterone on idiopathic steatorrhea, diagnosis of ulcers, dieting in colitis ulcerosa, protamine zinc insulin, roentgen therapy in carcinoma of the esophagus, the unexpected improvement in the metabolism due to intestinal baths and the significance of cell content of gastric juice.

Personal

Prof. Friedrich Suter, professor of urology in Basel, celebrated his seventieth birthday.

Dr. Otto Veraguth, associate professor of physical therapy in Zurich and director of the university institute for physical therapeutics, retired. Prof. Kurt von Neergard, his assistant for many years, was appointed to succeed him.

Military Use of Hotels

The Swiss federal council has resolved to use hotels for military and medical purposes. Rates for compensation have been set up.

Deaths

Prof. Charles Edouard Monnier, a pediatric surgeon in Zurich, died in his sixty-fifth year.

Marriages

RICHARD ALEXANDER HAMILTON, Springfield, Ky., to Miss Evelyn Elizabeth Patterson of Chattanooga, Tenn., July 12.

DAVID W. GOLTMAN to Miss Mary Helen Slattery, both of Memphis, Tenn., at Hernando, Miss., July 2.

FRANCIS F. TALBOT, Niagara Falls, N. Y., to Miss Florence O'Donoghue of Washington, D. C., July 15.

SAM MARSHALL COOPER, Knoxville, Tenn., to Miss Evelyn Lorraine Williams in New York, July 12.

JESSE GORDON SEASTRUNK, Columbia, S. C., to Miss Elizabeth Allen Parrott of Charleston, July 6.

WILLIAM SPENCER FAST, Atchison, Kan., to Miss Jane Adele Poindexter of Kansas City, Mo., July 10.

RICHARD L. PEARSE, Durham, N. C., to Miss Harriet Isobel Taggart of Tidioote, Pa., July 12.

ALBERT CHARLES ESPOSITO to Miss Vernon Elizabeth Dodson, both of Lexington, Ky., July 17.

PAUL JAMES AZAR, Washington, La., to Miss Mary Agnes Saloom of La Fayette, July 15.

WILLIAM REID PITTS, Glen Alpine, N. C., to Miss Elizabeth Creamer of Brooklyn, July 10.

GORDON S. FESSLER, Cincinnati, to Miss Ida Marie Lettieri of Shelby, Ohio, June 29.

WILLIAM B. ARMSTRONG to Miss Henrietta Collier, both of Atlanta, Ga., August 1.

THOMAS JOSEPH HARRIGAN, Altoona, Pa., to Miss Regina Ruth Stevens, July 17.

GEORGE HENRY ZERBST, Sumter, S. C., to DR. HILLA SHERIFF of Columbia, July 10.

SAMUEL J. HYMAN to Miss Cecelia Fisher, both of Inkster, Mich., July 16.

ALFRED A. GOGLIA, Boston, to Miss Molly Goglia of Bristol, R. I., in July.

Deaths

Howard Lincoln Snyder @ Winfield, Kan.; Jefferson Medical College of Philadelphia, 1904; member of the House of Delegates of the American Medical Association from 1936 to 1940; past president of the Kansas Medical Society; member of the board of governors of the American College of Surgeons; state chairman of the American Society for the Control of Cancer; member of the board of regents of the state of Kansas, which has under its supervision all affairs incident to state schools; surgeon on the staff of St. Mary's Hospital and the William Newton Memorial Hospital; aged 61; died, August 16, of coronary occlusion, hypertension and arteriosclerosis.

Everett Foster Jones @ Wichita Falls, Texas; University of Texas School of Medicine, Galveston, 1908; fellow of the American College of Surgeons; past president of the Wichita County Medical Society; served during the World War; past president of the Texas Railway Surgeons' Association; on the staffs of the Wichita Falls Clinic-Hospital and Wichita General Hospital; aged 55; died, July 15, of coronary artery disease.

John William Moore @ Charleston, W. Va.; University and Bellevue Hospital Medical College, New York, 1899; fellow of the American College of Physicians; served during the World War; at one time a medical missionary; superintendent of the Mountain State Hospital; formerly superintendent of the Charleston General Hospital; aged 70; died, July 20, of coronary thrombosis and arteriosclerosis.

Herbert William Jones, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; member of the Minnesota State Medical Association; at one time clinical assistant in medicine at his alma mater; formerly on the staffs of the Northwestern Hospital, City Hospital and the Asbury Hospital; aged 67; died, July 10, of heart disease.

Sidney Israel @ Houston, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1908; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society; on the staff of the Jefferson Davis Hospital; aged 53; died, July 17, of acute coronary occlusion.

Herman Orsen Seipel, Valparaiso, Ind.; Chicago College of Medicine and Surgery, 1914; member of the Indiana State Medical Association; formerly health officer of Valparaiso and county coroner; county health officer; on the staff of the Porter Memorial Hospital; served during the World War; aged 54; died, July 19, of coronary occlusion.

Charles Eliot Brown, Leavenworth, Kan.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1904; member of the Kansas Medical Society; formerly county health officer; aged 62; died, June 17, in the Cushing Memorial Hospital of empyema of the gallbladder and hypertensive heart disease.

Joseph Pink Harris @ Midlothian, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1918; past president of the Ellis County Medical Society; served during the World War; aged 57; died, May 18, in a hospital at Waxahachie of injuries received in an automobile accident.

Sterling Price Boothe, Cuero, Texas; University of Tennessee Medical Department, Nashville, 1906; member of the State Medical Association of Texas; served during the World War; on the staff of the Lutheran Hospital; aged 56; died, July 25, in the Nix Hospital, San Antonio, of pneumonia.

Mary Theresa Muldoon @ Waltham, Mass.; Tufts College Medical School, Boston, 1915; member of the New England Society of Psychiatry; on the staff of the Walter E. Fernald State School; aged 46; died, July 18, in the New England Hospital for Women and Children, Boston.

Dennis William Heffernan, Framingham, Mass.; Tufts College Medical School, Boston, 1910; fellow of the American College of Surgeons; served during the World War; aged 55; on the staff of the Framingham Union Hospital, where he died, July 22, of carcinoma of the pancreas.

Wallace Hanger Livingston @ Santa Fe, N. M.; Medical Department of Tulane University of Louisiana, New Orleans, 1909; past president of the New Mexico Board of Medical Examiners; aged 55; died, May 25, of pulmonary tuberculosis.

John Irvin Maris, Paoli, Ind.; Hospital College of Medicine, Louisville, Ky., 1903; member of the Indiana State Medical Association; president of the school board; served during the World War; aged 60; died, July 15, of coronary occlusion.

Albert Luke Stubbs, Hot Springs, S. D.; College of Physicians and Surgeons, Keokuk, Iowa, 1895; St. Louis College of Physicians and Surgeons, 1898; aged 74; died, June 12, at Edgemont of injuries received in an automobile accident.

Lewis Hunker, Moberly, Mo.; Washington University School of Medicine, St. Louis, 1903; member of the Missouri State Medical Association; aged 61; died, June 25, when he severed his left brachial artery.

Eugene Elmo May, Birmingham, Ala.; University of Nashville (Tenn.) Medical Department, 1900; member of the Medical Association of the State of Alabama; aged 62; died, July 23, of cerebral hemorrhage.

Murray Ross Watson, Mineral City, Ohio; Michigan College of Medicine and Surgery, Detroit, 1898; member of the Ohio State Medical Association; aged 64; died, July 14, of coronary thrombosis.

John Randolph Sledge, Stamford, Texas; College of American Medicine and Surgery, Atlanta, Ga., 1876; formerly health officer and mayor of Stamford; aged 84; died, June 16, of pneumonia.

Ralph Mott Erwin, Portland, Ore.; Chicago College of Medicine and Surgery, 1908; for many years county coroner; aged 55; died, July 12, in the Hahnemann Hospital of coronary thrombosis.

Harry E. Cover, Bantam, Ohio; Medical College of Ohio, Cincinnati, 1897; member of the Ohio State Medical Association; aged 68; died, July 22, of arteriosclerosis and chronic nephritis.

Barton Martin Winters, Goodville, Pa.; Jefferson Medical College of Philadelphia, 1877; aged 85; died, July 22, in Washington, D. C., of hypertensive heart disease and pulmonary edema.

Irvin Rue Peter, Wallace, Mo.; Northwestern Medical College, St. Joseph, 1886; Jefferson Medical College of Philadelphia, 1891; aged 75; died, July 23, of cerebral embolism.

Albert Allen Absher @ Sibley, Ill.; College of Physicians and Surgeons of Chicago, 1893; aged 71; died, July 20, in the Brokaw Hospital, Normal, of cerebral hemorrhage.

Charles Barton Lawrence, Columbia, Mo.; University of Louisville (Ky.) Medical Department, 1890; aged 73; died, May 18, following an operation on the prostate.

William Frederick Roberts, Delaware, Ohio; Harvard Medical School, Boston, 1902; aged 66; died, June 30, of cerebral hemorrhage and fracture of the hip.

Benning M. Kennon, McRae, Ga.; Atlanta Medical College, 1889; member of the Medical Association of Georgia; aged 78; died, June 29, of diabetes mellitus.

William Murray Winn @ St. Louis; National University of Arts and Sciences Medical Department, St. Louis, 1918; aged 46; died, May 14, of mitral stenosis.

Arthur Leon Brown, Riverside, Calif.; Medical College of Ohio, Cincinnati, 1896; served during the World War; aged 67; died, June 24, of coronary occlusion.

LACK OF EVIDENCE FOR CHRONIC CARBON MONOXIDE POISONING

To the Editor:—Whether there really is such a disease as that termed "chronic carbon monoxide poisoning," as a consequence of prolonged or repeated exposure to small amounts of the monoxide and continuing after the exposure is stopped, is very doubtful. Certainly its importance in many cases is less medical than legal and financial as a basis for claims for damages to be awarded by a compensation commissioner or a court of law. There is a large literature presenting numerous cases, described with clinical fulness and accuracy in respect to the symptoms of the disorder but with little or no evidence that the patients had ever been exposed to any significant extent to carbon monoxide.

If, then, numerous false claims are not to be bolstered by such papers, it is essential that writers on this subject should be required to report evidence as to the analytic method by which the amount of carbon monoxide in the air or in the blood was determined, how much was found and how long the exposure continued. Such a requirement would at once deprive the greater part of the literature in this field of all evidential value.

The lack of such evidence is exemplified in a paper by Drs. Beck, Schulze and Suter entitled "Carbon Monoxide—A Domestic Hazard with Especial Reference to the Problem in West Virginia" (*THE JOURNAL*, July 6, p. 1) as well as by the previous papers by Dr. Beck and his associates there cited. Among the conditions alleged to be due to carbon monoxide are diseases of the central nervous system, cardiovascular system and gastrointestinal system, and specifically encephalitis, epilepsy, multiple sclerosis, tetany, petechial hemorrhages, coronary thrombosis, cardiac dilatation, hemiplegia, syncope attacks, emotional episodes, visual disturbances, various forms of neuroses and psychoses, some with marked mental deterioration, ataxia, myalgia, muscular twitching, stiff and painful joints and angina pectoris. This is not the entire list of disorders alleged to be induced by repeated exposure to low concentrations of carbon monoxide but is sufficient in view of the fact that all these disorders are known to occur from other causes, and that in this paper no real evidence is presented that in the cases reported carbon monoxide was involved to any appreciable degree. Such involvement or causation is assumed merely on the basis of blood counts somewhat above normal in some cases and below normal in others: conditions that may also occur apart from carbon monoxide.

It appears that in West Virginia natural gas is extensively used for domestic cooking and heating, that the appliances in which the gas is burned are often without flue connections, and that during cold weather windows are rarely opened either by day or by night. Now natural gas is methane, which is no more poisonous than nitrogen, the chief constituent of air. Natural gas contains no trace of carbon monoxide. With a good supply of air to a flame of methane the gas burns with no production of carbon monoxide. What is produced is heat, water vapor and an atmosphere that is stuffy and unhealthful. No appreciable decrease of oxygen or increase of carbon dioxide in the air of the room so heated is usually involved. If the occupants exhibit poor health, it is fair to assume that bad ventilation may be a factor. But without positive demonstration of the presence of carbon monoxide by analysis of the air or the blood, no inference of "chronic carbon monoxide poisoning" is justifiable. Certainly not to the extent of the varied disorders listed.

The proverbial belief in regard to "chronic carbon monoxide poisoning" had its chief origin in the cases of prolonged asphyxiation by city gas, which were once common but are now rare. The small gas lighting fixtures then used in bedrooms were easily turned on accidentally, and as the small stream of gas flowed into the room the victim was exposed to a gradually increasing concentration of carbon monoxide. Often it was insufficient to cause immediate death by acute asphyxia but was sufficient over many hours to induce lasting damage to the brain. Today carbon monoxide asphyxiation commonly occurs in garages and kitchens and is generally acute and brief. Since the introduction of inhalation resuscitation, the large majority of cases fall into one or other of two classes: that in which the victims die immediately and that in which they recover rapidly and completely. But even in the cases of permanent damage that do still occasionally occur, the term "chronic carbon monoxide poisoning" is a misnomer. Before the patient comes out of coma the last trace of carbon monoxide has been eliminated from his blood. A better term would be permanent postasphyxial myelitis.

The question remains whether repeated exposures to amounts of carbon monoxide only sufficient to induce a headache but falling considerably short of rendering a man unable to stand or drive a car can do more than impair health temporarily. At present the probability is that termination of the unhealthful condition is always rapidly followed by return to health. Certainly the men who drive taxis in our larger cities and those who work in repair shops, although liable to all the disorders mentioned by Dr. Beck and his co-authors, have not yet been shown to be appreciably more liable than the rest of the population. We all breathe some carbon monoxide nearly every day of our lives.

The expression "chronic poisoning" can be properly applied only to the action of substances that are protoplasmic poisons and that may accumulate in the body. Lead is a typical example. Carbon monoxide, on the contrary, is rapidly eliminated by respiration, and its action while in the blood is wholly due to the temporary displacement of oxygen. The anoxia due to carbon monoxide acts essentially as does that induced by the low pressure of the air (i. e. oxygen deficiency) at great altitudes. The headache of mountain sickness and that of a temporary 20 or 30 per cent saturation of the blood with carbon monoxide are identical. Yet, given time for compensatory physiologic adjustments—of which an increase of red corpuscles in the blood is one—men are quite healthy at Denver and even on Pike's Peak.

It would be a valuable service if the board of health in one of our cities would institute an investigation by a gas analyst and a clinician jointly with regard to the amounts of carbon monoxide in the atmosphere in as many automobile repair shops as possible and as to the health and symptoms of disease of the mechanics who work in them. Experiments in this laboratory have shown that in dogs repeated asphyxiations of the severest character—just short of death—are required to induce any considerable impairment of health.

YANDELL HENDERSON, PH.D., New Haven, Conn.

[This letter was referred to Dr. Beck, who replies:]

To the Editor:—The criticism offered by Dr. Yandell Henderson, of our article in *THE JOURNAL*, July 6, affords me an opportunity to discuss some phases of the subject which have been misconstrued.

On some of the most salient points I agree with Dr. Henderson. This is with respect to the use of the term "chronic carbon monoxide poisoning." My associates and I have endeavored to make a clear distinction between what we regard as simple carbon monoxide anoxemia and the more chronic forms with organic changes occurring as residual manifestations of acute asphyxiation or the secondary effects of severe and protracted (chronic) anoxemia.

I have frequently called attention to the fact that the term "chronic carbon monoxide poisoning" was misleading. In an article on slow carbon monoxide asphyxiation in *THE JOURNAL*, Sept. 26, 1936, I made the following statement: "Chronic carbon monoxide anoxemia would designate the true nature of the condition better than 'chronic carbon monoxide poisoning,' as the latter is not only a misnomer but is actually misleading." If Dr. Henderson will read the article carefully in which he criticizes the use of the term "chronic carbon monoxide poisoning," he will not find mention of the words "poison" or "poisoning" or any reference to the term "chronic carbon monoxide poisoning."

However, I have used it in my previously published articles. This was done for the reason that the average physician is not familiar with any other term designating the condition. Moreover, articles on the subject, either in textbooks or in medical journals, invariably appear in the index under the caption "carbon monoxide poisoning." In the *Index of the Surgeon General's Library*, twenty finely printed pages are devoted to the bibliography on carbon monoxide. In eighteen of these pages references are listed specifically under the heading of "Carbon Monoxide Poisoning." The list includes extensive bibliographies under "chronic carbon monoxide poisoning" covering the English, French, German, Italian and Spanish literature. In my observations extending over many years, I discovered nothing new clinically on the subject and failed to find a single phenomenon which had not been previously fully described.

The bibliography on "Carbon Monoxide Poisoning: Manifestations, Mental and Neurological," covers a full page, and the pathology another page. A careful review of the literature furnishes ample evidence that serious damage to such structures as the brain, heart and other organs may result from carbon monoxide gas and that a variety of clinical syndromes naturally develop on such a pathologic-anatomic basis. The underlying pathologic changes occurring in the brain and central nervous system give rise to the many "conditions" which Dr. Henderson states are alleged to be due to carbon monoxide. It is well established that many of the "conditions" referred to—encephalitis, epilepsy, hemiplegia, syncopal attacks, emotional episodes, visual disturbances, neuroses, psychoses, mental deterioration and ataxia—are not disease entities but merely symptoms which, as a composite, express a single encephalitic or encephalomyelitic process.

In our series of 150 cases studied, thirteen exhibited definite signs and symptoms of chronic encephalitis, including practically the entire list mentioned. Here again, in this group of cases, I am somewhat in agreement with Dr. Henderson when he acknowledges that carbon monoxide does produce cerebral lesions and suggests as a better term "permanant postasphyxial myelitis." However, from a careful review of the literature and from our own clinical observations covering a period of twenty years, I would prefer to use the term "carbon monoxide or post-asphyxial encephalitis," and, to make it more inclusive, "encephalomyelitis."

The symptoms referable to the heart can be explained on the same pathologic-anatomic basis, the result of anoxemia. It is difficult to explain without attributing the cause to carbon monoxide why among 150 persons who were unquestionably exposed to the gas over long periods encephalitis occurred in one in every twelve and epilepsy in one in every seventeen patients admitted, when among those not exposed encephalitis occurred in only one in 198 and epilepsy in one in 148. These statistics are compiled from our own clinic records and deserve serious consideration.

As syndromes resulting from the effects of carbon monoxide can best be determined by careful clinical investigation, our approach to the subject has been primarily from the clinical side, and the results obtained have been correlated as far as possible with laboratory studies. The latter, exclusive of the routine urinalysis, blood count and serologic tests, included in selected cases the quantitative determination of carbon monoxide in the air by gas analysis or by the Mines Safety Appliance Company's carbon monoxide indicator.

For the mere detection of gas, palladium chloride was frequently used. The determination of carbon monoxide in the blood was made in some of our cases by the pyrotannic acid method (Sayers and Yant); in others, in which a more accurate quantitative determination was desired, the Van Slyke method was employed.

However, when one considers that the episodes causing the damage have usually occurred from exposures many months or even years before, the diagnostic significance of carbon monoxide in the air or in the blood dwindles to naught in these chronic or residual forms. Many of the cases studied were of years' duration. All the patients gave a history of one or repeated daily exposures with symptoms characteristic of anoxemia and of obtaining relief in fresh air, improvement of heating conditions or change of residence. In those cases presenting residual manifestations a history of anoxemia antedated the onset of symptoms.

Realizing the valuable services a board of health could render in instituting an investigation by a gas analyst and clinician conjointly, we have already taken advantage of the opportunity and concluded an investigation which was even broader in scope but confined largely to the study of the domestic problem. The survey was conducted under a grant provided for the purpose and was sponsored by the Research Committee of the University of West Virginia, aided by such agencies as the public utilities, the State Department of Health of West Virginia, the West Virginia Geological Survey, Cities Service Company of New York and our diagnostic clinic. An analysis of the natural gas from the wells was furnished by the state geological department. The condition of gas consuming appliances, the facilities for proper ventilation and the determination of the amount of carbon monoxide present were investigated by sanitary and gas engineers. Blood examinations for carbon monoxide saturation were made by Mr. Anderson of the Johns Hopkins University, using the Van Slyke method. Electrocardiographic studies were also made. The time of exposure, the length of residence in gas heated homes, the health of the occupants and many other details were included in the survey.

The results, which will be published later, furnish convincing proof of the correctness of our assertion and that we have made no unwarranted claims in stating that carbon monoxide may produce chronic states of ill health in the nature of clinical syndromes such as we have described.

HARVEY G. BECK, M.D., Baltimore.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

LITTLE HAZARD FROM ENAMELWARE

To the Editor:—Have there even been any ill effects reported from the chipped particles of enamel used in surfacing kitchen utensils? This enamelware often chips and I have been asked whether the ingestion of even inconsiderable amounts might prove to be harmful.

M.D., Ohio.

ANSWER.—Formulas for vitreous enamels vary extensively, but in the main the constituents appear to contain metallic silicates. Metallic oxides are employed to impart desired colors such as cobalt for blue, cobalt and manganese for violet, copper and chromium for green. Lead and arsenic formerly enjoyed wide use but for kitchen utensils have to some extent disappeared. Theoretically these enamels contain poisonous ingredients, but practically chemical injuries are not to be anticipated from any proper usage of these utensils or from the ingestion of small flakes of enamelware. High insolubility even in gastrointestinal juices assures comparative safety. Occasional claims are made of mechanical injuries from the cutting or irritating action of enamel flakes much akin to ingested glass fragments. As a rule such claims are without merit. Large scales such as might nick the esophagus are likely to be detected in the mouth. The mass action of a few small particles is so slight as to make harm improbable. The importance formerly attached to this class of foreign bodies in the gastrointestinal tract, and particularly small glass fragments, probably exaggerated the extent of any real harm produced.

AIR INSUFFLATIONS AND OXYGEN FOR TUBERCULOUS COLITIS

To the Editor:—Could you suggest a treatment other than rest, diet and vitamin therapy for a 3 months old tuberculous colitis in a patient with a long-standing but healing pulmonary tuberculosis? It has come to my attention that oxygen or air insufflations have been used in many cases with success. If this is so, could you outline the procedure or give me some references on the subject?

M.D., South Carolina.

ANSWER.—Pneumoperitoneum or oxyperitoneum has been used by many physicians for patients who have tuberculosis of various parts of the digestive tract, including the colon. The air or oxygen may be introduced into the peritoneal cavity by an ordinary artificial pneumothorax apparatus. The needle is introduced approximately two fingerbreadths to the left and 1 inch below the umbilicus. One does not obtain a negative manometer reading as in the pleural cavity; in fact, there usually is no oscillation when the needle first enters the peritoneal cavity. When the needle is introduced slowly through the abdominal wall, some resistance is met until it enters the peritoneal cavity. After the needle is inserted one should draw back on the plunger of the syringe to make sure that the tip of the needle is not in a blood vessel, as gas embolus has occasionally occurred during introduction of air into the peritoneal cavity. From 300 to 500 cc. of air is allowed to flow into the peritoneal cavity. The absorption rate is fast when oxygen is employed, and therefore the treatment should be repeated once or twice each week. Examination of the abdomen with the fluoroscope is a reasonably accurate means of determining when a sufficient amount of air or oxygen is present, and the frequency of refills can therefore be determined in this manner. The treatment may be continued as long as it seems beneficial, as indicated by relief from symptoms. This is not a curative procedure, but many patients state that it gives them considerable relief from symptoms.

It has been suggested that oxygen be introduced directly into the small intestine through a duodenal tube or into the colon through a rectal tube. When this is done great care should be taken to prevent the entrance of too much oxygen at one time, as it may cause severe pain. There is no satisfactory evidence available as to the benefit of such treatment, and therefore it should be discouraged unless further experimental work proves it to be of value.

In 1938 Fine and his co-workers (*Ann. Surg.* 107:1 [Jan.] 1938) showed that the inhalation of 100 per cent oxygen would decompress the distended abdomen after surgical operation within twelve to twenty-four hours. The best results were obtained when the Wangensteen method of suction was employed

in conjunction with the inhalation of oxygen. Fine's work has been confirmed by Boothby (*THE JOURNAL*, Aug. 5, 1939, p. 477), Lovelace (*Minnesota Med.* 22:117 [Feb.] 1939) and Mayo (*West Virginia M. J.* 35:520 [Nov.] 1939). Indeed they, with Bulbulian, have devised special masks which provide for the inhalation of oxygen at any desired percentage up to 100. They have found this of great value following surgery and also in peritonitis. They believe it is also of value in certain infections, particularly those produced by anaerobic organisms. When pure oxygen is inhaled, the oxygen content of arterial blood is increased from 10 to 15 per cent. When the patient inhales 100 per cent oxygen it has been shown that the nitrogen quickly disappears from the lungs, the nitrogen in the blood is eliminated by way of the lungs in a few minutes, that in the tissues is given up to the blood, which in turn throws it off in the lungs, and thus more oxygen is permitted to enter the tissues.

There is no reason to suspect that the inhalation of 100 per cent oxygen has any harmful effect on tubercle bacilli; indeed, they are aerobic. Nevertheless the patient with intestinal tuberculosis may suffer from distention and he may also have peritonitis, and therefore he may be relieved by the Wangensteen suction method plus the administration of 100 per cent oxygen. It has been shown that 100 per cent oxygen may be breathed for forty-eight hours without any evidence of irritation of the lungs. However, beyond this time it is thought best to decrease the concentration. Here, again, one has not a curative but only a palliative measure.

SKELETAL DEMINERALIZATION AND THEELIN (ESTRONE)

To the Editor:—Roentgenologists observe that most people who fracture their hips and bodies of the vertebrae are women past the menopause. The thought comes that the cessation of ovarian function might influence calcium metabolism. If that is true, would a hormone like theelin help in the deposition of lime in the bones?

Philip J. Lukens, M.D., Ambler, Pa.

ANSWER.—There is no well substantiated evidence that theelin is of value in the deposition of lime in the bones of an otherwise normal person either before or after the menopause. Spontaneous fractures of the hips or vertebral bodies are extremely rare and usually secondary to specific bone destructive lesions, such as neoplasms. The fact that fractures of this type in elderly persons are more common in women than in men can probably be explained on the basis that men, on the average, are physically more active than women not only late in life but throughout adult life. There is some evidence that atrophy of the skeleton, which is common in elderly persons and is called by various terms, including senile osteoporosis, results from years of ingestion of diets low in calcium content, from faulty absorption of calcium salts from the gastrointestinal tract, or from the wasting which is always associated with a decrease in the physical activity of the individual. It is quite possible that a combination of these three causes may explain the extreme demineralization of the human skeleton in elderly women, but it is also found not infrequently in elderly men. The actual increase in incidence of fractures in women over the men can be explained best by the fact that women fall much more often, and in falling they are not as adept as men, who have been more active physically, in arresting the fall with their hands.

IS ACETOPHENETIDIN HABIT FORMING?

To the Editor:—I should like to know whether or not there have been any cases reported of addiction to phenocetin. Can this drug be considered a habit forming drug and are there ever "withdrawal symptoms" associated with the discontinuance of this drug after one has taken it a while?

M.D., Georgia.

ANSWER.—The answer depends on one's concept of "drug habit" and "withdrawal symptoms." There are infinite gradations between the "habit" of chewing gum, at one extreme, and heroin addiction at the other. "Withdrawal symptoms" similarly grade insensibly from mild desire and discomfort to intense craving and physical collapse. Most people take acetophenetidin, acetanilid or acetylsalicylic acid only occasionally and for definite indications such as headache, pain or colds. Those who have habitual headache are inclined to take drugs habitually and may develop chronic poisoning, especially cyanosis, but they can stop without marked craving or other withdrawal symptoms. A few individuals appear to feel a positive elation or even inebriation, and these are more likely to use the drugs to excess and to feel the withdrawal more keenly and may object quite vigorously, especially if they have a neurotic or hysterical temperament; but violent reactions are rare and may be charged to inherent nervous irritability more than to these drugs.

MELTING CAPSULES

To the Editor:—In the following prescription used for certain cases of hypertension the patient has had difficulty in preserving the capsules without melting. However, this has been overcome by putting a small amount of absorbent cotton in the container and keeping the capsules in a cool place. The pharmacist informs me that the ingredient responsible for this is calcium iodobenzenate, and the decomposition can be controlled by putting this ingredient inside a separate capsule, which is then placed inside the regular capsule. I would appreciate knowing if this procedure can be eliminated or, if not, do you have any suggestions to make in regard to compounding the mixture without having it decompose? The prescription is as follows: soluble phenobarbital 15 grains (1 Gm.), theophylline with ethylenediamine 60 grains (4 Gm.), calcium iodobenzenate 90 grains (6 Gm.). Mix and divide into 45 capsules.

M.D., West Virginia.

ANSWER:—The softening of the capsules by this prescription mixture might be prevented by the addition of kaolin or powdered althea. These are both inert. Or sodium iodide in a correspondingly smaller amount could be substituted for the calcium iodobenzenate with the same therapeutic results. If the capsules are taken with a full glass of water or after a meal, that quantity of sodium iodide given in a solid form would not be irritating. In any case the capsules should be kept in a cool dry place.

TRAUMA AND MYXOSARCOMA

To the Editor:—Please give me information regarding the possibility of trauma causing, exacerbating or hastening the development of a myxosarcoma of the upper part of the leg in one who uses this portion of his leg in climbing poles and the like. Where might I find authoritative information on this subject? Could an acute minor injury cause a rapid progression of such a growth? The tumor seemed to be in the muscles. Could it possibly be a rhabdomyoma rather than a myxosarcoma?

W. L. Hartman, M.D., South Orange, N. J.

ANSWER:—There is no evidence that trauma can act as the sole causative factor in the development of a myxosarcoma of the upper part of the leg. There have been cases in which the evidence seemed to indicate that trauma has acted as a contributing factor in the development of such a lesion. There is an extensive literature on the relation between trauma and tumors. This can be readily found by reference to the *Quarterly Cumulative Index Medicus*. It is unlikely that an acute minor injury would cause a rapid development of such a growth. As a rule it is not difficult to distinguish microscopically between rhabdomyosarcoma and myxosarcoma.

MAPHARSEN AND LOOSE STOOLS

To the Editor:—I should like to know whether or not the full benefit is obtained from maphorsen by a patient in whom neorarsphenamine causes vomiting and in whom maphorsen causes from one to three or four loose and profuse watery stools. I am afraid I am losing the benefit of the drug, and although I started out using this drug every fourth day, I do not seem to obtain any better results by giving it at weekly intervals. Should I use a smaller dose than 0.06 Gm. for a man weighing 185 pounds (84 Kg.)?

M.D., West Virginia.

ANSWER:—If the patient has vomiting following neorarsphenamine, it probably was wise to change to mapharsen. It is possible that he is slightly arsenic sensitive, but as long as he has nothing worse than three or four loose and profuse watery stools there seems to be no reason why this treatment should not be continued. Probably it would not be wise to use the drug every fourth day, however. Since the man weighs 185 pounds, the dose of 60 mg. given about every five days or once a week for a series of ten injections might be advisable. He might also be given some preparation which would have a tendency to render him a little costive for ten or twelve hours after the injection. It is not felt that the patient is losing the benefit of the drug simply because he has a few loose, watery stools.

COLON AFTER COLOSTOMY

To the Editor:—From several months to several years after a permanent colostomy is performed, what happens to the integrity of the colon as far as function, musculature and size of the lumen are concerned?

M.D., New York.

ANSWER:—There have been no studies reported as to the function and structure of the colon after permanent colostomy, probably because this procedure is performed usually for the relief of obstruction from carcinoma and the patients do not live long enough to allow such detailed observations. One patient, examined a year after colostomy, showed no significant change in the distal colon. A second patient nine years after colostomy likewise had a normal rectum. Operation several years after ileostomy in chronic ulcerative colitis has revealed, in some cases, a narrowing of the large bowel, the lumen being from one fourth to one third its usual size. It is known experimen-

tally that months after permanent colostomy in monkeys there is a distinct atrophy of the distal bowel. Patients with colostomy frequently pass small grayish masses by rectum, doubtless representing accumulations of mucus and epithelial debris. This was noted in a patient eighteen years after a colostomy by Franz (*Ztschr. f. Geburtsh. u. Gynäk.* 85:598, 1923) and apparently mistaken for "recurring tumor." There is no evidence available as to the microscopic structure of the musculature of the colon after permanent colostomy.

DIET OF MOTHER AND FETAL SIZE

To the Editor:—I have never been able to settle to my satisfaction the controversy as to whether restriction of diet during pregnancy will affect the weight of the baby. Will you discuss this? Furthermore, in conjunction with this question, is it possible by any means to govern the size of the unborn baby's head and is it true that the weight of the baby and the size of the baby's body are relatively unimportant since the body follows easily wherever the head can go?

W. A. Dawson, M.D., Dalhart, Texas.

ANSWER:—It is probably true that the consensus of obstetricians is that the bulk of the baby can be limited. This is done by restricting the sugars and starches and some restriction of fluid during the last trimester of pregnancy. Care should be exercised that the actual requirements of a balanced diet are not disturbed. The restriction of food does not affect the length of the baby or the size of its head. These are probably more largely determined by heredity. It is not true that the weight and size of the baby are unimportant, because delivery is often complicated by bulk and excessive size of the bony structure as well as by a large head.

EFFECTS OF CHORIONIC GONADOTROPIN

To the Editor:—Are there any remarkable side effects from the therapeutic use of chorionic gonadotropin in either men or women? M.D., Idaho.

ANSWER:—Chorionic gonadotropin is the preparation from the urine of pregnant women which is known to stimulate the interstitial cell tissue of the testicles and to cause atresia or a type of atrophy of the ovarian follicles in women. It apparently maintains a corpus luteum after this has once formed in the course of the normal cycle of ovarian activity in women. These fundamental reactions are the basis for its therapeutic use. Except for slight local reactions in some instances there are no other demonstrable effects of such chorionic gonadotropin in human beings. A detailed Council report on this material will be found in *THE JOURNAL*, Feb. 10, 1940, page 487.

INTRAVENOUS DEXTROSE SOLUTION NOT
HARMFUL TO KIDNEYS

To the Editor:—Is there any evidence tending to show that 50 cc. of 50 per cent dextrose injected intravenously would be detrimental to kidneys already seriously impaired?

James T. Quattlebaum, M.D., Columbo, S. C.

ANSWER:—There is no evidence to indicate that 50 cc. of 50 per cent dextrose injected intravenously causes any damage to diseased kidneys. Rapid injection of several times this amount might cause sufficient acute circulatory disturbance to affect renal blood flow, but even this is a rather remote possibility.

PELVIC DIAMETERS

To the Editor:—Where can I find references to correlation between the bieristal and bitrochanteric diameters and body heights? I am particularly interested in orietles which will give this information by chronological age. I should like to have information on both male and female pelvises.

M.D., New York.

ANSWER:—Information of this nature exists to some extent but is scattered and has not as yet been summarized. The correspondent should consult references to measurements on the pelvis, and on children and adolescents, in the *Index Catalogue of the Library of the Surgeon General's Office*, U. S. Army, and in the *Quarterly Cumulative Index Medicus*.

"BLINDNESS FROM HEMORRHAGE INTO
OPTIC NERVE"

To the Editor:—With regard to your reply to the query about blindness from hemorrhage into the optic nerve canal (*The Journal*, August 3, p. 404) I have it on the authority of Foster Moore (*Medical Ophthalmology* 1922) that hemorrhage into the sheath of the optic nerve does not cause blindness. A better explanation of this case would be damage to the nerve by a tracture through the optic foramen. In that event the prognosis was bad from the start and evacuation of the blood or any other operation would not have helped.

E. C. Ellett, M.D., Memphis, Tenn.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, August 24, page 636.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 17-19. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.
ALASKA: Juneau, Sept. 3. Sec., Dr. W. W. Council, Box 561, Juneau.

ARIZONA: *Written*. Phoenix, Oct. 1. *Reciprocity*. Phoenix, Oct. 2. Sec., Dr. J. H. Patterson, 326 Security Bldg., Phoenix.

ARKANSAS: *Regular*. Little Rock, Nov. 7-8. Sec., Dr. D. L. Owens, Harrison. *Eclectic*. Little Rock, Nov. 7. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California). San Francisco, Oct. 2. *Written examination*. Sacramento, Oct. 21-24. Sec., Dr. Charles B. Pinkham, 1020 N St., Sacramento.

COLORADO: Denver, Oct. 1-4. Applications must be on file not later than Sept. 17. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Written*. Hartford, Nov. 12-13. *Endorsement*. Hartford, Nov. 26. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homeopathic*. Derby, Nov. 12-13. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: July 8-10. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: Washington, Nov. 11-12. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Tampa, Nov. 18-19. Sec., Dr. W. M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 8-9. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Jan. 8-11. Sec., Dr. James A. Morgan, 48 Young Building, Honolulu.

IDaho: Boise, Oct. 1. Dir., Bureau of Occupational License, Mr. H. B. Whittlesley, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 1-3. Superintendent of Registration, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 17-19. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, Citizens Trust Building, Fort Wayne.

KANSAS: Topeka, Dec. 10-11. Sec., Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

KENTUCKY: Louisville, Dec. 3-5. Sec., State Board of Health, Dr. A. T. McCormack, 620 Third St., Louisville.

MAINE: Portland, Nov. 12-13. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Medical*. Baltimore, Dec. 10-13. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic*. Baltimore, Dec. 10-11. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 12-14. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Lansing, Oct. 9-11. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: Minneapolis, Oct. 15-17. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: *Reciprocity*. Helena, Sept. 30. *Written*. Helena, Oct. 1-2. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEW JERSEY: Trenton, Oct. 15-16. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 7-8. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Sept. 23-26. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Building, Albany.

NORTH CAROLINA: *Reciprocity*. Durham, Dec. 3. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 7-10. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: Oklahoma City, Dec. 11. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: *Reciprocity*. Portland, October. *Written*. Portland, Jan. 14-16. Exec. Sec., Miss Lorette M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: Philadelphia, January. Dir., Bureau of Professional Licensing, 358 Education Bldg., Harrisburg.

PUERTO RICO: San Juan, Sept. 3. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

RHODE ISLAND: Providence, Oct. 3-4. Sec., Division of Examination, Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, Nov. 12. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, Jan. 21-22. Dir., Medical Licensure, Dr. J. F. D. Cook, Pierre.

TEXAS: Austin, Nov. 25-27. Sec., Dr. T. J. Crowe, 918-920 Mercantile Bldg., Dallas.

VERMONT: Burlington, Feb. 11. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 4-6. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WEST VIRGINIA: Morgantown, Oct. 31-Nov. 2. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: Madison, Jan. 14-17. Sec., Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, October. Sec., Dr. M. C. Keith, Capitol Building, Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Tucson, Sept. 17. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson.

COLORADO: Denver, Sept. 16-17. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: New Haven, Oct. 12. Chairman, State Board of Healing Arts, Dr. Charles M. Bakewell, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, Oct. 21-22. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Gainesville, Nov. 1. Applications must be on file not later than Sept. 16. Sec., Dr. John F. Conn, John B. Stetson University, De Land.

IOWA: Des Moines, Oct. 8. Dir., Division of Licensure and Registration, Mr. H. W. Greffe, Capitol Building, Des Moines.

MINNESOTA: Minneapolis, Oct. 1-2. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis.

NEBRASKA: Lincoln, Oct. 1-2. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

OREGON: Portland, Oct. 26. Sec., Mr. Charles D. Bryne, State Board of Higher Education, University of Oregon, Eugene.

SOUTH DAKOTA: *Examination*. Yankton, Dec. 6-7. *Endorsement*. Dec. 21. Sec., Dr. Gregg M. Evans, Yankton.

WISCONSIN: Madison, Sept. 21. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

Mississippi June Report

Dr. R. N. Whitfield, assistant secretary, State Board of Health, reports the written examination for medical licensure held at Jackson, June 26-28, 1940. The examination covered twelve subjects and included ninety-six questions. An average of 75 per cent was required to pass. Forty-two candidates were examined, all of whom passed. Twenty-five physicians were licensed to practice medicine by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
The School of Medicine of the Division of the Biological Sciences.....	(1937)		88
University of Louisville School of Medicine.....	(1940)	83.4	85, 88.7
Tulane University of Louisiana School of Medicine....	(1940)		80.5
		82.9, 84.5, 84.8, 85, 85.4, 85.5, 85.8, 86.2, 86.4, 86.6, 86.8, 87, 87.6, 87.9, 88, 88, 88.5, 88.8, 89, 89.5, 89.5, 89.7, 90.4, 90.6, 91.5

Kentucky June Report

Dr. A. T. McCormack, secretary, State Board of Health of Kentucky, reports the written examination for medical licensure held at Louisville, June 6-8, 1940. The examination covered eleven subjects and included 110 questions. An average of 70 per cent was required to pass. Sixty-eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Louisville School of Medicine.....	(1937)		81,
(1938) 80, (1940) 76, 77, 77, 78, 78, 78, 79, 79, 79, 79, 79, 80, 80, 80, 80, 80, 80, 80, 80, 80, 81, 81, 81, 81, 81, 81, 81, 81, 82, 82, 82, 82, 82, 82, 82, 83, 83, 83, 83, 83, 83, 83, 84, 84, 84, 84, 84, 85, 85, 85, 85			
University of Cincinnati College of Medicine.....	(1939)		85
University of Pennsylvania School of Medicine.....	(1937)		81,
(1940) 84			

Twenty-two physicians were licensed to practice medicine by reciprocity and one physician so licensed by endorsement from February 8 through July 13. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with

Book Notices

Tuberculosis of Bone and Joint. By G. R. Girdlestone, M.A., B.M., F.R.C.S., Nuffield Professor of Orthopaedic Surgery, Oxford. Cloth. Price, \$8.75. Pp. 265, with 161 illustrations. New York & London: Oxford University Press, 1940.

Orthopedic surgeons have long been aware of the apparent difference between the course of the average case of bone and joint tuberculosis in the United States and the same disease treated under similar conditions in the British Isles or on the European continent. Some of the orthopedic surgeons may have developed theories which attempt to explain this. This excellent treatise by Girdlestone is the first completely adequate discussion of the general subject of bone and joint tuberculosis, based on an extensive clinical experience and analyzed by a thoroughly competent clinical observer, which has appeared in the modern literature. The author emphasizes the fact that bone and joint tuberculosis in the United States and Canada has been reduced by as much as 75 per cent through enforced pasteurization of milk and the elimination of tuberculous cattle from the dairy herds in these countries. Less effective measures toward public hygiene in the British Isles and on the European continent are probably the explanation for the fact that the incidence of this disease in children continues to be high. There is also a suggestion that the better results obtained in the treatment of bone and joint tuberculosis by bed rest or plaster cast, without the aid of surgery, in the sanatoriums of Europe may be explained by the fact that the majority of these patients are suffering from the bovine type of tuberculosis, while in America today the disease is, in more than 90 per cent of the cases, produced by the human tubercle bacillus. This tends to bear out a statement occasionally made, but without actual data to substantiate it, that the human tubercle bacillus is more virulent and the disease caused by this organism more difficult to treat and control than that caused by the bovine bacillus. More than the average surgeon in the British Isles and in Europe, Girdlestone has utilized the adjunct surgical treatment and in selected cases has found it to be a most valuable aid in the cure of the disease. He states that "the fibrous ankylosis following conservative treatment is seldom permanently safe from recrudescence, and time alone does not bring safety." This is a statement with which the more widely experienced orthopedic surgeons in America will almost unanimously agree. This text and reference book is well illustrated with reproductions of excellent roentgenograms and photographs. The subject matter is subdivided according to the regions of the body most commonly involved. This is a book which can be safely recommended to physicians and surgeons, to medical students and to all those who are interested in the control of tuberculosis of the bones and joints.

The Challenge of Adolescence. By Ira S. Wile, M.S., M.D. Cloth. Price, \$3.50. Pp. 481. New York: Greenberg, Publisher, Inc., 1939.

Many books have been written to serve as textbooks in courses on adolescent psychology, but no volume was written prior to this one with the exception of Stanley Hall's out of date masterpiece which serves to cover the field of adolescence as an important field to the physician and the psychiatrist. While it is true that adolescence blends imperceptibly with childhood and adulthood, the physical changes which accompany it are noticeable and easily defined on the basis of numerous social problems with resultant mental, moral and familial conflicts. Wile has covered this whole aspect of adolescent psychology in modern fashion. The approach is what one would expect when considering the various factors of adolescence. As would be expected, the first chapter is devoted to the explanation and

definition of adolescence. Since adolescence is significant in the physical aspect first of all, and the ancillary problems of sexual adjustment and psychosexual evaluation at the same time, the first five chapters are devoted to an explanation of sex as the adolescent sees it and the physical and psychiatric foundation for various concepts. Going on from there, social conflicts and the intellectual and emotional problems which arise in this period are given careful consideration and culminate in a chapter, of deep significance, on unconscious factors in behavior. Naturally these factors are important only as they affect the adolescent's attitude toward the outside world, so that the remaining chapters are devoted to family influences, companions and recreation, religion and morals, economics and vocation, delinquency and crime and an interpretation of the psychologic changes during youth. This chapter is devoted to an examination of neuroses and psychoses of the adolescent, and the book closes with a discussion of politics and ethics with particular reference to youth movements. All in all, this book is a remarkable contribution to the literature of psychiatry and will give not only the psychiatrist but also the physician who wishes to enlighten himself, as well as teachers and others who have problems of adolescence to deal with, a great deal of insight and understanding of the growing youth.

Fourth Saranac Laboratory Symposium on Silicosis: An Official Transcript of the Fourth Saranac Laboratory Silicosis Symposium Held in Connection with the Trudeau School of Tuberculosis at Saranac Lake, N. Y., June 19 to 23, 1939. Edited by B. E. Kuehse, Vice President and Claims Manager, Employers Mutual Liability Insurance Co., Wausau, Wis. Paper. Price, \$3. Pp. 379, with 4 illustrations. Wausau, Wisconsin, 1939.

Silicosis is here treated broadly. As most of the basic facts of the etiology, pathology, roentgenology and diagnosis of the disease have been presented in previous symposiums, these topics are covered by relatively brief yet adequate reviews. The importance of the degree and type of exposure and individual variation in response is discussed by Cummings. Gardner explains the pathologic process and the relation of tuberculosis to silicosis. Riddell gives a summary of the clinical appearances in simple silicosis and in silicosis complicated by tuberculosis, emphasizing the importance of the infectious process in the causation of symptoms. Pendergrass covers the subject of pulmonary anatomy in healthy and silicotic individuals, with particular attention to the x-ray appearances. There is a paper by Drinker on the technics and interpretation of dust counts and analyses.

This basic groundwork having been established, the symposium goes on to some special considerations. These include the problem of estimating degrees of disability, for which McCann gives a fairly simple, objective method based on the measurement of vital capacity, a general evaluation of the functions of an examining clinic as distinct from the care of industrial injuries, the incidental abnormalities not related to dust exposure found in the lungs of workers, and the pathologic responses to inert dusts and to mixed dusts.

About half of the book is devoted to the discussion of dust hazards in specific industries, special attention being given to silica but other materials also being mentioned. Dolomite mining is stated to be free from the silicosis hazard unless the dolomite is mixed with sandstone, which is an unusual circumstance. While gypsum has no injurious effect of itself and may actually retard the development of silicosis in exposed workers, there are several minor processes in its preparation which may cause difficulty. These are subject to easy control. Conditions in the production of Portland cement are somewhat similar. Heavy dust concentrations are encountered, but few of the materials have sufficient free silica to be dangerous. Other factors also are operative to reduce the hazard. There is no evidence that either finished cement or its raw materials, as encountered in the industry, have any harmful effect on the lung. There is a very considerable hazard in the granite-cutting industry unless adequate exhaust systems are used. Such installations are feasible for most of the work, but some operations remain in which adequate control is very difficult. In foundries there is pronounced variation in the exposure to silica, depending on the nature of the work and on the amount of dust dispersed. In general there is not as much silicosis as might be expected. The control of tuberculosis by prompt diagnosis and isolation of

open cases is emphasized. Silicosis has been fairly common among hard coal miners but can be controlled by certain modifications of the working methods.

The final fourth of the book is given over to discussion of administrative and legal measures to be taken for the control of the disease. This is gone into in such detail that abbreviation here would do an injustice.

As is inevitable in reports of symposiums, there are a number of differences of opinion among the contributors. Some of these are resolved in the discussions, and in most instances supporting data are given which will allow the reader to arrive at a conclusion of his own. Unfortunately, the papers were not adequately edited. Several of them make pretty dull reading, are unnecessarily long and are sometimes ambiguous. There is an index which is fairly good.

Elementary Pathological Histology. By W. G. Barnard, F.R.C.P., Professor of Pathology, University of London, London. Second edition. Cloth. Price, 10s. Pp. 75, with 181 illustrations. London: H. K. Lewis & Co., Ltd., 1940.

This is an atlas of elementary pathologic histology intended for use on the bench when sections are being examined. It consists of well selected and generally excellently executed photomicrographs with a small number of diagrammatic sketches. Brief descriptions are placed on the pages opposite the illustrations. Each subject is ushered in by a concise and lucid introduction. The first thirty-four pages (one half of the whole book) are given to inflammations, to acute infections and to granulomas, seventeen pages to degenerations, to hypertrophy, to hyperplasia and to vascular disturbances, and the remaining eighteen pages to neoplasms. The book has apparently filled a need in England, as proved by the publication of a second edition. It may prove useful in this country for an elementary course in histopathology. However, it would have to be supplemented in many places, because the selection of the material was obviously arbitrary. The atlas may find another field of application in this country because of the requirement of some knowledge of pathology by the different specialty boards. Many specialists who have been away from school and from pathology for years could find in this book a pleasant and painless introduction to the rudiments of pathologic histology. A few critical remarks will not detract from the value of this, on the whole, well constructed book. One might question the definition of an abscess as a "localized focus of inflammation in the substance of a tissue or organ." One would hardly offer such a definition to a student. Several errors crept in, as "xanthoproteic reaction" and "the cells between these two positions are almost severely affected," both on page 47, or in the index, where hemosiderin is referred to page 18 instead of to page 10. The American student will have to use the term "giant cell tumor" instead of "osteoclastoma (myeloid sarcoma)" (fig. 144) if he expects to be understood by his fellow students, and chorion-epithelioma is also better known here than chorioncarcinoma. In view of the fine illustrations and the high quality of the paper and of the binding the price of the book is surprisingly low.

A Study of Experimental Tissue Reactions Following Intravenous Injections of Silica and Other Dusts. By F. W. Simson, M.B., Ch.B., and A. Sutherland Strachan, M.A., B.Sc., M.D. From the Department of Pathology, the South African Institute for Medical Research, Johannesburg. Publications of the South African Institute for Medical Research, No. XLV, Vol. IX. Edited by the Director. Paper. Pp. 95-122, with 25 plates. Johannesburg: The Institute, 1940.

Rabbits were given repeated ear vein injections of saline and aqueous suspensions of exceedingly fine quartz, Rand mine dust, sillimanite, orthoclase, muscovite, rutile, glass and mixtures of mine dust and coal. The total doses varied in animals that did not die prematurely between 60 and 360 mg. of material. The period of observation was likewise variable but for each dust some animals survived well over a year.

The authors note the occurrence of silica shock incident to injecting fine quartz and attribute it to change in the normal hydrogen concentration of the blood serum.

They note the development of typical silicotic lesions in the spleen, liver, lymph nodes and bone marrow on injecting quartz and mine dust and the inert type of reaction caused by the other pure minerals, thus confirming observations made in the Saranac Laboratory, where this method originated. They discovered

lesions in the kidneys, pancreas and adrenal glands which the reviewer has not encountered in examining scores of rabbits similarly treated. It is possible that the renal lesions may have been due to the chronic nephritis so common in rabbits; or possibly the high frequency of intercurrent infections (fourteen out of forty-nine rabbits) may have been responsible for these changes and the ones described elsewhere. The reviewer would question the conclusion that this group of changes constitutes evidence of poisoning resulting from circulating soluble silica, since he has failed to observe such changes in rabbits injected with many doses of different sized silica particles.

The absence of pulmonary reaction in animals injected with such fine particles (from 67 to 86 per cent of them 0.8 micron or less in diameter) is a cause for comment, but the reviewer has shown that such fine particles are mechanically carried through the pulmonary capillaries and but few are retained in the lungs. Only when the particles are in excess of 10 microns are many of them held in this organ. The fineness of the dust particles also explains the high frequency of silica shock and the tendency of the silica injections to cause early death. They consider the question of individual susceptibility but conclude that it is not a factor, as all animals show silica reactions in some organs. However, it should be pointed out that the doses of such very active sized particles as they have used are too great to expect differences in reaction from possible differences in individual susceptibility. They note the similarity of the splenic lesions to those in Banti's disease and suggest that in each condition absorption of toxic substances from the liver may be the cause. They fail to emphasize, however, that in the silica animals the spleens are themselves the site of many specific silicotic lesions. They call attention to the "proliferation" and "dedifferentiation" of bile duct epithelium that are so common in advanced silicotic cirrhosis of the rabbit liver and rightly emphasize the subsequent absence of a malignant condition.

Die angioarchitektonische areale Gliederung der Grosshirnrinde auf Grund vollkommener Gefässinjektionspräparate vom Gehirn des Macacus rhesus anatomisch dargestellt. Von Dr. phil. et med. Richard Arwed Pfeifer, Professor der Hirnforschung an der Universität Leipzig. Paper. Price, 38 marks. Pp. 352, with 293 illustrations. Leipzig: Georg Thieme, 1940.

This is a profusely illustrated monograph concerning the angio-architectonics of the cerebral cortex of *Macacus rhesus*. The preparations were made by the author's injection method. The author maintains that angio-architectonics is now an autonomous discipline comparable to cytoarchitectonics and myelo-architectonics. On the basis of his studies Pfeifer has prepared an elaborate map of the cerebral cortex of the macaque and gives detailed photographs of the vascular pattern of the most important areas. The differences in vascularization are sometimes obvious; in other cases considerable imagination is necessary to see the boundaries. One wonders what results the author would have arrived at if he had had no cyto-architectonic maps before him. The fields outlined are not identical with those of Brodmann but the general correspondence is striking. It would serve no purpose to go into detail concerning the topographic results of this study. The book is of no use to the practitioner of medicine. Its appeal will be to a small group of students of the cerebral cortex, to whom this careful and detailed work with its numerous excellent plates will be of great interest.

Sir Thomas Roddick: His Work in Medicine and Public Life. By R. E. MacDermot, M.D. Cloth. Price, \$2. Pp. 160, with 12 illustrations. New York & Toronto: Macmillan Company, 1938.

The mention of the name Roddick, especially in medical circles in Canada, immediately brings to mind one event documented in the annals of Canadian statutes as the Roddick bill, an act of Parliament which provided for the Medical Council of Canada. One would have to understand a good deal about the Canadian constitution with its British North America act and provincial autonomy to appreciate the full significance of Dr. Roddick's achievement, because it was an achievement, largely of one man, to persuade the authorities to carry this act into effect; and Dr. Roddick will always be remembered north of the forty-ninth parallel of latitude for this accomplishment. Dr. MacDermot in this little volume tells the story simply but

involved palmar also gives a glance at Roddick the man, Roddick 90, prudent, with his quaint sense of humor. We are then introduced to Roddick the professional man of keen insight and ability. One who likes biography which presents in stereoscopic fashion the various facets which go to make up an unusual man, written in a style which is easy to read, will enjoy this book.

Transition Years: The Modern Approach to "the Change" in Womanhood. By Joseph Rety, M.D. Cloth. Price, \$1.75. Pp. 168, with one illustration. New York: Greenberg, Publisher, Inc., 1940.

This excellent book reveals the author as one who has a real clinical knowledge of the problem he is discussing. The simple, even homely, style is peculiarly well adapted to the group for which it is written; i. e., the present generation of middle-aged women, most of whom have had little or no reliable information in this field. Each chapter contains elementary yet adequate material to clarify its meaning. Substitution of "uterus" for "womb" might be suggested as an additional educational feature. The chapter on the ductless glands is well handled. The discussion of the "change," the description of the many symptoms of the climacteric, both physical and psychologic, the recommended daily routine, the relationship of the climacteric and sexual life, the admonitions to husbands and the final chapter addressed to widows and spinsters all paint a picture which only a physician of wide experience and clear perception could do so well.

Pathological Histology. By Robertson F. Ogilvie, M.D., F.R.C.P., Senior Pathologist, Royal Infirmary, Edinburgh. Foreword by A. Murray Drennan, M.D., F.R.C.P., Professor of Pathology, University of Edinburgh. Cloth. Price, \$8.50. Pp. 332, with 220 photomicrographs in color by T. C. Dodds, F.R.P.S., F.I.B.P., Senior Technician, Pathology Department, University of Edinburgh. Baltimore: William Wood & Company, 1940.

The principal feature of this small volume is the illustration of its text by 220 photomicrographs in color. It is in fact an atlas of histopathology and is intended to be supplementary to a standard textbook. The text is rather brief and is limited mainly to histologic descriptions. Most of the illustrations are good and will be helpful in teaching histopathology. The illustrations of blood cells, however, do not show nuclear structure clearly and are inferior to good drawings. Photomicrographs in color have the advantage that they resemble the stained section closely, yet they usually do not show the details of structure as sharply as good photomicrographs in black and white. This work will prove useful as a supplementary textbook.

Penny Marsh, Supervisor of Public Health Nurses. By Dorothy Deming, R.N. Cloth. Price, \$2. Pp. 303, with 9 illustrations by Dorothea Warren. New York: Dodd, Mead & Company, 1939.

This is a sequel to the volume "Penny Marsh: Public Health Nurse." It details the further adventures of Penelope Marsh, R.N., in the field of public health nursing and describes her experience and life as a supervisor. It is interestingly written and the information on public health nursing problems is cleverly interspersed between adventure and a love interest. The book can be recommended for the seniors in high school and for the young women in college as a part of the vocational guidance library.

Selected Writings of Sir Charles Sherrington: A Testimonial Presented by the Neurologists Forming the Guarantors of the Journal BRAIN. Compiled and edited by D. Denry-Brown. Cloth. Price, \$7.50. Pp. 532, with 86 illustrations. New York: Paul B. Hoeber, Inc., 1940.

This book was published by the guarantors of the journal *Brain*, themselves neurologists and physiologists, because they wished to make some of Sherrington's reprints and extracts of his published papers more readily available for those interested in biologic, physiologic and clinical medical sciences. In this excellent compilation one will find the original descriptions of the spinal animal, the experimental isolation of skin and muscle segmentation, observations on reflexes and their interaction, the motor representation in the primate cortex and the fundamental proof of reciprocal innervation and postural reflexes. The conception of central inhibition is also discussed. This book is

highly recommended to the neurologist, physiologist and psychologist. It will serve as an excellent reference manual for all of Sherrington's contributions.

Workers' Health Hazards—Today and Tomorrow. Detection and Control of Silicosis and Other Occupational Diseases. What New York State has done and the Job Ahead. A Progress Report to the Legislature of the State of New York Submitted by Frieda S. Miller, Industrial Commissioner. Paper. Pp. 31, with illustrations. New York: Department of Labor, 1940.

This brochure is a progress report addressed in popular language to the state legislators on the activities in the field of health protection of workers, undertaken by the Division of Industrial Hygiene of the New York State Department of Labor. For technical discussions of actual work performed, other scientific reports and statements of this agency should be consulted.

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Cancer of Pancreas Allegedly Due to Trauma.—When the blade of a road grader which he was operating or helping to operate for Wayne County, Neb., struck a telephone line anchor on Sept. 22, 1936, Lessman allegedly was struck on the chest by a crank handle and on the right thigh and hip by another lever. He was thrown from the grader but was able to climb back on and continue his work. He made no complaint of his injury to any one except his wife until six months later. According to his wife, when he arrived home from work on the day of the accident he complained of injuries to his right knee and hip and to his chest, on which was visible a "bruised mark" in the region of the right nipple. In March 1937 he consulted an osteopath who treated him for pleurisy and strapped his hip and lower part of his pelvis. In the early part of November 1937 he filed a claim for compensation under the workmen's compensation act of Nebraska. During the latter part of that month he became jaundiced. In December, fifteen months after the accident, he died. An autopsy revealed that the cause of death was carcinoma of the head of the pancreas. Lessman's widow was then substituted as claimant. She contended that Lessman's death from cancer of the pancreas had been caused by the accident. The compensation court found to the contrary and denied compensation, but on a rehearing it reversed its decision and awarded compensation. From a judgment of the district court, Wayne County, affirming that award, the defendants, Wayne County and its insurance carrier, appealed to the Supreme Court of Nebraska.

A medical witness for the defendants testified that there is grave doubt whether trauma has any influence on the development of cancer; that it would be extremely difficult for the head of the pancreas, because of its location, to be injured by trauma and that a blow sufficiently severe to drive the abdominal wall back so far that it might reach the head of the pancreas would more likely injure other organs, such as the stomach and liver. Another medical witness for the defendants, a pathologist who had done research work on cancer, testified that he was not entirely convinced that a blow or trauma will cause cancer although in some cases "acute trauma" occasionally appeared to play a causative part, and that in all his experience he had never seen a case of cancer due to trauma. These medical witnesses testified that a blow of sufficient severity to injure the pancreas would cause the person to suffer a shock such as having his breath knocked out, intense pain, rigidity of the muscles, nausea and vomiting and would render him unable to continue his work.

The evidence, said the Supreme Court, was conflicting as to whether Lessman sustained an accidental injury on Sept. 22, 1936. Assuming that an accident did occur at or about that time, it was impossible for the alleged injuries to Lessman's chest under the right nipple and to the right knee and hip to have also caused an injury to the pancreas. The medical testi-

mony showed that if that organ had been he would have suffered, among other things, vomiting and could not have immediately back on the grader and continued to work without complaint. If, continued the court, contrary to the evidence, it is assumed for purposes of argument that in some unknown manner Lessman's pancreas was slightly injured, it is highly speculative whether such injury produced or in any way affected the carcinoma from which he died. From the evidence it appeared that no cancer has ever been deliberately produced experimentally by trauma. Although severe injuries to the human body have been followed by "cancer" at the point of injury, the tumor involved has usually been the "violently malignant form of sarcoma." Even in these cases medical authorities are sharply divided as to whether such injuries simply reveal and accelerate the growth of a "cancer" already present or actually cause the sarcoma itself. In the judgment of the court the evidence failed to show with reasonable certainty that Lessman's death had been caused by an accidental injury in the course of his employment. Awards of compensation, said the court, cannot be based on mere speculation, possibilities or probabilities. Accordingly, the judgment of the district court upholding the award of compensation was reversed.—*Wayne County v. Lessman (Neb.)*, 285 N. W. 579.

Malpractice: Liability of Hospital for Negligence of Intern and Nurse.—The plaintiff was a pay patient in the hospital operated for profit by the defendant, the Stuart Circle Hospital Corporation. As a part of its business the hospital undertook, through nurses and interns employed by it, to give the plaintiff nursing service and medical treatment. Preparatory to the taking of roentgenograms of the plaintiff's gallbladder an intern, on the written order of the plaintiff's attending physician, attempted to administer an intravenous injection of a dye solution consisting of from 50 to 60 per cent free iodine, a caustic substance which if injected outside of the vein "will seriously burn human tissue." The intern injected approximately 17 cc. of the solution outside of the vein into the surrounding tissue in the plaintiff's right arm with the result that she suffered pain and her right elbow became stiffened. At the attending physician's direction a graduate nurse employed by the hospital applied to the plaintiff's right arm a hot compress over which she placed "surgical wax" and a hot water bottle wrapped in a bath towel. One and one-half hours later a student nurse discovered that the plaintiff's arm was very red. Due to either excessive heat from the hot compress or too long a period of application, or both, the plaintiff received "considerable first and slightly second degree burns" on her upper forearm with subsequent scarring. As the result of the injection of the dye solution she became practically an invalid with a partial sensory paralysis of her right radial nerve, a "thirty degree disability" in the use of her right arm, loss of the use of two fingers and the thumb of her right hand, insomnia and excessive nervousness. She brought suit against the defendant corporation for malpractice and from a judgment in her favor for \$13,000 the defendant brought error to the Supreme Court of Appeals of Virginia.

The defendant contended that under the medical practice act of Virginia, which prohibits the practice of medicine by any one except a licensed physician, a hospital is not permitted to practice medicine, that it cannot make a valid contract to render medical services which involve the exercise of professional skill and judgment and so it cannot be held liable for a breach of such a contract or for damages due to negligence of one of its interns while performing an act requiring the exercise of such skill and judgment. However, the medical practice act provides that nothing therein shall be construed "to affect or interfere in any way with the operation of any hospital . . . if there be a licensed practitioner resident or practicing therein." While this exemption, said the Supreme Court of Appeals, does not permit a hospital to engage in the practice of medicine within the intent of the broad statutory meaning of that term, it does authorize such institutions to engage in so much of the practice of medicine as enables it to render to its patients such necessary routine medical care and attention as is customarily engaged in by hospitals in the proper conduct of their businesses.

The implied contract on the part of the hospital corporation, continued the court, to undertake for compensation to render

to the plaintiff through its agents or employees of which the routine medical treatment and nursing services of which the condition might require was neither illegal nor ultra vires. The contract was not to furnish a competent and skilled physician but an intern whose relationship with the hospital was different from that of the patient's attending physician or of the members of the hospital staff. A hospital is not responsible for the acts of an attending physician whether he is a member of its staff or an outsider except when by special contract it has assumed such responsibility, because he is an independent contractor and is subject to no control by the hospital in the exercise of his professional skill and judgment. An intern, on the other hand, is not an independent contractor but is selected, employed, directed, supervised and paid by the hospital. He does not hold himself out as practicing medicine and does not have patients of his own. While the duties and functions of a nurse and an intern may vary, there is no substantial difference in their relationship to the patient in the hospital, and they both act as servants or agents of their employer, the hospital. The court concluded, therefore, that a private hospital operated for profit and held out to the public as furnishing to its patients medical and nursing services is responsible to a patient for the negligent acts of its intern and nurse employed by it and acting under its supervision and control, in the performance of their routine duties.

In the judgment of the court the evidence adduced was sufficient to justify the trial court's finding that both the intern and the nurse had been negligent. In its opinion the verdict for \$13,000 was not excessive because the plaintiff's injuries were serious and the medical witnesses were unable to forecast whether or not her physical and "neurotic condition" would improve. Accordingly, the judgment of the trial court in favor of the plaintiff was affirmed.—*Stuart Circle Hospital Corporation v. Curry (Va.)*, 3 S. E. (2d) 153.

involved palmar fascia. The result has been satisfactory in about 90 per cent of the cases. Subcutaneous section of the constricting bands of palmar fascia is a satisfactory method of treatment in certain cases. A carefully managed program of physical therapy is necessary. A combination of excision, splinting and physical therapy results in a useful functioning extremity.

Acute Appendicitis.—King reviews a series of cases of appendicitis observed at the Binghamton City Hospital during the years 1934-1937 inclusive and during the year 1929-1930. During the four years 1934-1937, 1,628 patients were operated on primarily for appendicitis. There were 824 chronic cases and 804 acute cases. The author points out that the fact that appendicitis mortality as reflected from the surveys by insurance companies and from the United States Bureau of Census showed a definite downward trend in the past ten years is not borne out in this series; all this despite the fact that the incidence of early and more favorable cases has been steadily increasing. The mortality rate among the cases complicated by peritonitis has failed to improve. Acute uncomplicated appendicitis had a mortality rate of 0.34 per cent, a figure which is almost irreducible. Appendical abscess had a mortality rate of 14.3 per cent, which is too high. A short but representative experience with bacteriophage in the treatment of ruptured appendicitis indicates that it may be a valuable adjunct in the treatment of these difficult cases. Improvement in appendicitis mortality, which is improvement in peritonitis mortality, calls for a revision of the present methods of treatment and the introduction of such new features as have been tried and proved superior. The key to lowering of the mortality from appendicitis lies in reducing the incidence of peritonitis.

Acute Stomatitis.—Smith and Johnson used chromic acid in local treatment of gingivostomatitis for twenty years. The gums and ulcers are dried carefully with a swab and another swab is dipped into the chromic acid solution (from 5 to 7 per cent in water) and applied directly to the ulcers and inflamed gums. Some of the solution is gently worked in between the gums and the teeth. The general treatment is that of any febrile illness. Chromic acid has a definite analgesic effect. The application causes little or no pain. Patients can eat with more comfort for several hours after a treatment. The inflammation of the gums begins to improve after two or three treatments (two a day) and in from forty-eight to seventy-two hours there is a distinct change. The records of the Children's Medical Service at Bellevue Hospital show about twenty cases a year. Sixty-eight of the old cases were selected for analysis. Boys and girls between the ages of 1 to 3 years were equally affected. Thirty-six were treated with chromic acid and thirty-two with perborate or gentian violet. The total duration of the disease was roughly the same in the two groups, about thirteen days. But the duration of the disease after starting chromic acid treatment averaged about two days (seven and a half as compared to nine and a half) less than in patients treated otherwise. Twelve patients with gingivostomatitis were treated more systematically; six had symptoms from one to two days before treatment was begun and they were improved in from twenty-four to forty-eight hours and practically well in about four days. The time necessary for a complete return to normal depends on the duration of the disease before the treatment is started. In several private patients, in whom treatment was begun as soon as the gum margins became red and isolated ulcers appeared, the mouth healed in three or four days.

Prevention of Rickets in Premature Infants.—Zelson gave single massive doses of various vitamin D preparations to forty-six premature infants. Twenty infants were given a single parenteral dose of 600,000 units of crystalline vitamin D₂ or D₃ in 0.7 cc. of peanut oil and 0.3 cc. of ether. The others received a single oral dose of from 200,000 to 500,000 units of another preparation. No signs of toxicity or calcium casts in the urine followed the administration of these massive doses. Local infiltrations at the site of the intramuscular injection of vitamin D did not occur. Only seventeen infants were

followed up for from forty-four to 279 days. The others, after discharge from the hospital, did not return or could be followed only for a shorter period. Rickets appeared in only one. The others did not show any clinical, x-ray or chemical sign of rickets up to the time of the last examination. From the evidence it seems reasonable to assume that rickets in premature infants can be prevented for three months by the parenteral administration, although not necessarily by the oral administration, of one single dose of 600,000 units of vitamin D. The definite need for prophylactic doses of vitamin D probably varies with the individual child, depending on term and season of birth, race, constitution, diet, social factors and geographic and climatic conditions. The dose must be adapted to the infant. Premature infants need the first dose approximately in the third week of life. It should be repeated three months later. Subsequently, premature infants resemble infants born at term in their vitamin D requirement. The highest incidence of rickets occurs in the first winter of life. To secure complete protection two doses, one in October and one in January, are generally advocated. This is repeated in the second winter of life, and in the third winter one preventive dose in December might suffice.

Typhus in Louisiana.—Musser states that typhus is becoming more frequently observed in the United States, particularly in the Southern states, involving the urban and rural population. The author reported his second case in May 1929, while in 1939 there were 115 cases reported to the Louisiana State Board of Health, Division of Epidemiology. This indicates the rapidity with which typhus has become an epidemiologic problem. In Louisiana the disease occurs both in the summer and in the winter. It is entirely of the endemic type. Endemic typhus has an incubation period of from seven to fourteen days. While there may be irregular prodromes, the disease usually strikes suddenly with a chill or chilliness, followed by high fever, marked headache and severe prostration. The temperature rises persistently and is at its maximum in from five to seven days. The fever is continuous, is maintained for approximately a week

and then falls to normal in from five to seven days. The characteristic exanthem, which is really of supreme diagnostic importance, occurs on the fourth or fifth day of the disease. The symptoms of endemic typhus are milder than of the typhoid and infinitely more innocuous than epidemic typhus. The death rate is correspondingly much less. A patient rarely dies of typhus. The author believes that the problem of endemic typhus in the South can be explained by the fact that here the milder winter climate, adequate food supply and failure to rat proof buildings results in a heavy rat population, whereas in the North the necessity of erecting buildings of concrete and brick to keep out the winter and the lack of food for a rat makes the disease relatively rare. The only possible control of endemic typhus is to cut down or minimize the rat population which carries the flea. Continuous trapping and poisoning of rats should be kept up wherever rats are found in a large number.

Vaginal Antisepsis and Puerperal Morbidity.—Ziegler and Austin consider the vagina of a woman in labor as potentially infected in that it may contain pathogenic bacteria. According to them the so-called normally sterile vagina in the adult female does not exist. Constant drainage into the vagina from the cervix and easy and repeated contamination from without conspire to defeat the establishment and maintenance of vaginal asepsis. During labor infected contents of cervical glands are expressed into the birth canal by the ironing out processes of effacement and dilatation of the cervix. The obstetrician is the only surgeon who makes no attempt to sterilize his operative field—the vagina. If it is infected when labor

begins, the most perfect technic of preparation which does not include the vagina will not be sufficient to prevent puerperal infection in the presence of the abrasions, contusions and lacerations which commonly occur, and especially when the hands of the operator or the forceps blades are passed through an unprepared bacteria-laden vagina into the uterus. If antiseptics kill bacteria, decrease their numbers and attenuate their virulence there is no reason why they should not be used in the vagina as regularly as they are used elsewhere. During the last seven years vaginal antiseptics has been used as a matter of routine at the Elizabeth Steel Magee Hospital in about 17,000 cases of labor. It has been applied by means of the Kolpospray—an atomizer operated by compressed air with a pressure of about 35 pounds. The vagina is rapidly flooded and is thoroughly cleansed and flushed by the force of the spray. The secretions are mixed with the solution and blown out through the vents in the rear of the encasing tip as the escaping air under pressure returns unhindered to the atmosphere. The antiseptic used was a 1:2,500 solution of tincture of merthiolate. Each patient is sprayed at the beginning of labor and every eight hours thereafter until the completion of labor. Should the membranes rupture before labor begins, the spraying is done every twelve hours until labor begins. Vaginas are sprayed before each examination and before all operative procedures, including cesarean section, irrespective of when sprayed previously. When possible, an hour should elapse after spraying before operative procedures are undertaken. A spraying should be timed to follow complete effacement of the cervix when possible. If an enema is to be given, it must precede preparation and spraying. A comparison of 5,140 cases, 2,749 deliveries in 1932 before antiseptics was practiced and 2,391 deliveries in 1937 (the fifth year of its routine employment) shows that of the first group 45.47 per cent were afebrile, 39.32 per cent had fevers from 99.2 to 100.2 F. and 15.21 per cent had fevers higher than 100.4 F. The respective figures for the 1937 group were 48.47, 42.37 and 9.16 per cent. The last percentage includes 287 unsprayed vaginas. In the 1932 group there were eight deaths from peritonitis, nine from septicemia, five from hemorrhage, two from pulmonary complications, one from a cardiac ailment, seven from toxemia and four miscellaneous. The corresponding figures for the 1937 group were three, zero, four, four, two, zero and one. The authors state that vaginal antiseptics is an addition to and not a substitute for asepsis as practiced in every well conducted maternity. It will not lessen morbidity due to infection introduced from without during the puerperium.

Age and Parity as Factors in Puerperal Fatality.—Yerushalmy and his associates discuss the bearing of age and parity as factors in puerperal mortality. His study is based on the 258,525 infants born in New York State (exclusive of New York City) during 1936, 1937 and 1938. The maternal death certificate was matched with the birth or stillbirth certificate of the infant, and the death certificate of every infant who died within one month of birth was matched with its birth certificate. The risk to the mother associated with the delivery of an offspring of viable age is defined as "puerperal fatality." The author found that the puerperal fatality rate was high for

mothers delivered of their first child (28.2 per 10,000 deliveries), lowest for the mothers of third births (18.5) and highest for mothers delivered of their eighth and ninth child (63.4). The rate for combined infant loss (late fetal and neonatal mortality) was also relatively high for first births (59.8 per thousand of total births), was at a minimum for second births (44.9) and increased thereafter with order of birth to a maximum (96.9) for births of the highest orders. The relative stillbirth rates by order of birth were similar to the relative puerperal fatality rates. The increase in puerperal fatality by order of birth embraces all causes of death. However, septicemia caused a smaller proportion of deaths among the higher orders of births, while toxemia was more frequent among first births and births of higher orders than among the intermediary births. Deaths from hemorrhage were less frequent among primiparas than among multiparas. The puerperal fatality increased with advancing parity among mothers whose infants survived the first month of life. More than 5 per cent of the deliveries terminated prematurely. The infant loss was eighteen times as high among the premature as among the full-term infants. Puerperal fatality was seven times as high when pregnancy terminated prematurely as when delivery was at term. The infant loss was relatively high among the youngest mothers, was lowest for mothers in their twenties and increased thereafter with the age of the mother. Puerperal fatality was at a minimum for the youngest mothers and increased sharply with advancing age. The puerperal fatality rate and the infant loss were independently related to the order of birth and the age of the mother. The puerperal fatality rate and the infant loss were relatively high when the father was young, low when the father was between 25 and 34 years of age and again high when the father was older. This variation is independent of the correlation between the ages of husband and wife. Similarly the variation in puerperal fatality by age of husband is not an expression of the relation between age of father and infant loss.

Crystalline Sulfanilamide in Compound Fractures.—Stuck and his co-workers report the use of crystalline sulfanilamide in twenty-six consecutive unselected cases of compound fractures. Twenty-one cases were fresh compound fractures seen shortly after the accident, and five were old compound frac-

tures in which chronic osteomyelitis had been present for many months. Primary union was obtained after operation in twenty-two. Osteomyelitis developed in two of the fresh cases (one a compound dislocation of the ankle, the other a badly macerated compound fracture of the tibia). Healing has not yet occurred in two of the old osteomyelitis cases. In contrast to the usual procedure all wounds were closed without drains and yet gas gangrene did not develop in any of the new cases. The local use of sulfanilamide does not in any way take the place of thorough cleansing and débridement of wounds. The administration of prophylactic antitetanus serum and antigas serum is likewise equally important. However, the authors believe that since the high local concentration of sulfanilamide seems to be specific against the gas-forming anaerobes and since antigas serum is not invariably effective it may be safe to omit its routine use. The prophylactic administration of roentgen therapy over compound wounds, which was a routine procedure, has been discontinued for they have complete confidence that gas gangrene will not develop in wounds treated with sulfanilamide. The oral prophylactic administration of sulfanilamide has been abandoned because they feel that high local concentrations of sulfanilamide are far more effective.

Sulfanilamide in Treatment of Undulant Fever.—Horn reviews twenty articles which report eighty-three cases of brucellosis treated with sulfanilamide or its derivatives. The daily dosage fluctuated from 1 to 6 Gm. and the total dosage from 7 to 72 Gm. The duration of treatment varied from thirty-six hours to twenty-three days and the reported results from failure to miraculous cures. However, a study of the compiled cases indicates a favorable influence on the subjective symptoms of the disease in the ratio of 2:1. This same ratio was elicited by the author in fifty-four cases treated with sulfanilamide or its derivatives. The toxic side effects were no different from those seen from its use in other conditions. Only two of the cases were acute. In one of these sulfanilamide has been given the credit for a cure on 40 grains (2.6 Gm.) daily for seventeen days, while the other patient failed to respond and died eight months later although she was given three additional courses of the drug. In the fifty-two chronic cases sulfanilamide was voted of value although a number of times the brucella organism was recovered from the feces after varying dosage and periods of sulfanilamide therapy. Small doses (2.3 Gm. daily) over a period of twenty-five days in the chronic cases seem to have a favorable effect. The courses are repeated every other month. Improvement appeared to be more consistent and more effective after the second than after the first course of treatment. The author believes that the provocative influence of sulfanilamide on the opsonocytaphagic index is of valuable diagnostic importance. Likewise he is convinced that it stimulates phagocytic protection and otherwise favorably influences the course of the disease in a satisfying majority of cases. He believes that the regular and consistent use of specific vaccine during and following sulfanilamide therapy is important; the one appears to complement the other.

Results in 427 Stored Blood Transfusions.—Stewart reports on 427 transfusions with blood stored for from an hour or two to thirty days. At first no attempt was made to use relatively fresh blood in cases in which it is now believed to be essential. The results in such cases tended to be disappointing. In the surgical cases the results appeared to be independent of the "age" of the blood. In such conditions as leukemia, various types of anemia, septicemia, toxemia and the like, blood is now used which has been in store for as short a time as possible, and the results have, by the same criteria, greatly improved. In fact, fresh blood appears to possess little if any superiority. With the stabilization of conditions it has become possible to keep in store the large stock of blood, not more than two or three days old, necessary for war emergencies. It was found that blood stored for not more than fourteen days does not increase the reaction incidence and that with blood stored for from five to ten days the incidence may be reduced. However in an emergency it would be justifiable to use blood stored for more than fourteen days for cases of severe acute hemorrhage. There were fifty-eight reactions. Among the 259 transfusions performed since January 1940 there were twenty-seven reactions. Stored blood should not be used indiscriminately. Certain patients should receive blood not more than two days old, as by that time a considerable proportion of the viable leukocytes has disappeared. In these cases the necessity for providing leukocytes outweighs the lessened reaction incidence obtainable with blood stored for from five to ten days. Older blood seems to be suitable when the object of the transfusion is to supply fluid and oxygen-carrying power. The advantages of a blood store are greatest only if blood is withdrawn so frequently that almost fresh blood is always available. Many cases requiring fresh blood are not emergencies, and transfusions for them can usually be arranged on the day when blood is being withdrawn for the store. In this way practically "direct" transfusions can be given and the inconvenience to donors minimized.

Synthetic Vitamin K in Hypoprothrombinemia.—Kark and Souter studied the vitamin K activity of a water-soluble derivative of 2-methyl-1, 4 naphthoquinone, administered intravenously or intramuscularly to eighteen patients with hypoprothrombinemia. The conditions in the patients were various but hypoprothrombinemia was a feature. There was a rapid rise in blood prothrombin concentration in nine cases after the administration of the compound. No toxic effects were observed. In most of these cases a relapse followed the discontinuance of therapy, and the blood prothrombin concentrations were again restored to normal by further treatment. In three cases there was active bleeding before treatment was begun. This was controlled within a few hours after its initiation. Discussing the cases that failed to respond to treatment, the authors state that whereas some patients with severe hepatic damage are apparently completely unable to produce prothrombin, others with most severe or most chronic hepatic disease produce prothrombin, but in quantities insufficient to maintain a normal level. The failure of response to the parenteral administration of vitamin K in these two groups of patients may be of some prognostic importance when considered along with the level at which the blood prothrombin concentration is maintained. All the patients of the first type died. The authors think it probable that in the future vitamin K or one of its analogues will be given as a routine before operation to patients suspected of having hypoprothrombinemia. However, such administration is not a guaranty that the blood prothrombin concentration will be raised to within normal limits. If the prothrombin level is low in spite of such treatment, blood transfusion is the only known therapeutic measure which can increase the prothrombin concentration.

Sulfamethylthiazole in Staphylococcal Infections.—Macdonald found that about half of the mice infected with staphylococci by the intraperitoneal or intravenous route and treated with sulfapyridine or sulfamethylthiazole lived for twenty-one days. Many of the mice surviving this length of time harbored the infecting organism and some still had abscesses in the kidneys. Treatment for only fifteen days may not have been sufficient, but it is fairly characteristic of the sulfonamide drugs that when they act they do so quickly. Some of the results obtained compare unfavorably with those of several experienced workers. It seems that both sulfapyridine and sulfamethylthiazole prevented many of the early deaths in staphylococcal infections of mice, and it is probable that both drugs are less efficient after abscesses have begun to form. None of the sulfonamide drugs are particularly active in the presence of pus, and the experiments with cutaneous abscesses may indicate that sulfamethylthiazole does not completely overcome this difficulty. There is little evidence that sulfamethylthiazole is as specific for staphylococcal infections as other sulfonamide compounds are for pneumococcal or for streptococcal infections.

Surgery for Hypoglycemia Caused by Adenomas of Islands of Langerhans.—Sauerbruch credits American investigators with having recognized in recent years a form of paroxysmal spontaneous hypoglycemia caused by hyperfunctioning of a benign pancreatic adenoma. Removal of the tumor effects a cure. The clinical picture begins with a sensation of hunger, fatigue and faintness. The patient feels weak in the knees and collapses; there are apathy, loss of orientation, stupor and somnolence. General or localized spasms may appear. The pupils become dilated and lose their reactivity. There may be foaming at the mouth and biting of the tongue or lips. As a rule there are labored respiration, rapid pulse and increased blood pressure. Symptoms resemble those of an epileptic attack. The patients after awakening fail to recollect the event. They recover within a few minutes if given sugar solution to drink; the recovery is even more rapid after intravenous injection of dextrose. The diagnosis of such an attack is usually one of epilepsy or brain tumor. Such was the experience of the author in three cases. The true nature of the condition was not recognized until repeated determinations of the sugar content of the lumbar punctate and of the blood had been made. An additional important sign of a pancreatic adenoma is the time of the appearance of the attacks. They generally appear in the morning, when the patient is still fasting, when he is hungry or after exertions or excitations; that is, always when the blood sugar level is physiologically low. Early operation is advisable. The detection of a tumor the size of a cherry stone or a cherry may be difficult. Frequently it can only be felt and in such a case splitting of the cortical layer is necessary. The pancreas is best exposed through the gastrocolic ligament. The author gives detailed clinical histories of two patients with hypoglycemia in whom recovery followed the removal of a langerhansian adenoma. The first patient was a girl aged 7, the second a woman aged 50. The author cites two more investigators who have each reported a recent case cured by extirpation of an insuloma.

Pathogenesis of Nonrenal Hypertension.—According to Siebeck it is now generally recognized that there are many disorders associated with temporary or permanent increase in blood pressure not caused by morbid changes in the kidneys. The differentiation of the renal from the nonrenal form of hypertension is often quite difficult, because it frequently depends on a history which is not reliable. The two forms differ in significance. In every severe chronic nephritis there exists the danger of gradual renal decay which finally results in renal insufficiency. In nonrenal hypertension, however, renal degeneration is rare, circulatory failure and cerebral disturbances being much more frequent complications. Investigations demonstrated that in the event of insufficient blood perfusion of the kidneys there develop "pressor substances" which circulate in the blood and produce a general vasoconstriction. Apparently they can be differentiated from other nonrenal pressor substances, such as were demonstrated by Marx in other forms of hypertension and in epilepsy. At the onset of acute nephritis the blood pressure is not dependent on the kidney. In scarlet fever, for example, hypertension often precedes the symptoms of nephritis. Moreover, the blood pressure may increase before pressor substances

appear in the blood. In chronic nephritis there is often no relationship between the degree of renal damage and the height of the blood pressure. Furthermore, it is known that in the later stages of nonrenal hypertension the kidneys may become involved. Nevertheless the etiology of nonrenal hypertension is not entirely obscure. The significance of the hereditary factor is no longer disputed and the fact that the nonrenal hypertension increases with age is also evident. The author observed repeatedly that hypertension may develop after acute infections even if there is no nephritis. He thinks that hereditary predisposition and damage caused by misuse of tobacco, restlessness and increased physical and psychic tension may also play their part, but he regards the role of infections as most important in the genesis of the nonrenal "essential" hypertension. For this reason infections, particularly chronic foci of infection, should be searched for and treated. If the hypertension has already become chronic the prospect of a cure or improvement is slight. Early treatment, therefore, is essential. Other methods of treatment should not be neglected. In view of the constitutional character of the disease, medicinal treatment is of value only to counteract temporary complaints and complications. A suitable regulation of the mode of life is of chief importance. There should be proper rest and relaxation, suitable arrangement of the daily tasks, calm acceptance of the tribulations of life, restriction of salt in the diet and liberal quantities of fruits and fruit juices, abstinence from tobacco and moderation in the consumption of wine and beer.

Monaldi's Suction Drainage of Pulmonary Cavities.—Wolf calls attention to Monaldi's method of suction drainage of tuberculous cavities of the lung. Monaldi succeeded in reducing and gradually closing tuberculous cavities by permanent conversion of the positive internal pressure into a negative one by means of suction drainage (introduction of a rubber catheter through the thoracic wall into the pulmonary cavity). Roentgenologic and anatomic observations proved that the atelectatic zones surrounding the cavities actually expand as a result of the negative pressure. Relatively recent cavernous processes have better prospects of cure than old cavities with rigid walls, but even cavities with rigid walls can be obliterated by the suction treatment. The chief indication for suction drainage is giant cavities which do not readily yield to the various collapse methods. Even extensive thoracoplasty often fails to produce a complete collapse of these giant cavities and the possibility of dissemination presents a constant danger for the patient. If the Monaldi method does not effect a complete cure, it at least reduces the size of the cavity and makes it amenable to operative intervention. Residual cavities which have undergone plastic operations can likewise be subjected to suction drainage. The author observed a surprising improvement in the subjective and objective condition of his patients as the immediate effect of suction drainage. Attacks of coughing ceased soon after the introduction of the catheter and toxic symptoms gradually decreased in the course of the following days and weeks. The temperature of febrile patients was reduced and this was accompanied by improvement in the general condition and in the appetite. The quantity of sputum decreased in all cases, and sputum retention, so frequent in giant cavities, did not occur. Better drainage brings about detoxication and rapid disappearance of toxic symptoms. Heart action improves and night sweats disappear.

*Ascorbic Acid in Treatment of Vomiting of Pregnancy. D. Taylor Gorostiaga.—p. 612.

Ascorbic Acid Therapy of Vomiting of Pregnancy.—Taylor Gorostiaga made observations on the behavior of ascorbic acid in normal pregnancy and pregnancy complicated by vomiting or toxemia. The experiments involved thirty women in the course of early pregnancy and ten normal women. Demole's test for saturation of ascorbic acid in the body was used. The test consists of making a preliminary quantitative determination of the elimination of ascorbic acid in the urine,

and administration to patients of ascorbic acid by mouth in daily doses of 300 mg. up to the appearance of ascorbic acid in the urine in the amount of about 5 mg. per hundred cubic centimeters of urine. This amount represents normal saturation of the body with ascorbic acid. The acuteness of organic deficiency of the substance is evaluated from the storage of ascorbic acid in the body, before appearance of the aforementioned approximate amount of the acid in the urine. The author found that a physiologic deficiency of from 600 to 900 mg. of ascorbic acid may exist in normal women. The deficiency reaches figures of about 1,200 mg. in normal pregnancy and of higher figures in gestosis and vomiting. Either condition is controlled by ascorbic acid treatment when hypovitaminosis C is present, except when neuropathic or other disorders predominate. The treatment consists of administration of ascorbic acid by mouth up to normal ascorbic acid saturation as shown by the elimination of about 5 mg. of the acid per hundred cubic centimeters of urine. Thereafter the saturation is maintained by administering 100 mg. of the acid daily.

*Effectiveness of Specific Virus Vaccine Therapy in Grip by Inhalation. A. V. Nechaev.—p. 25.

Inhalation of Virus Vaccine for Grip.—Nechaev reports the results obtained with inhalation of antigrip virus vaccine as observed in a group of 437 cases of epidemic grip and 198 cases of sporadic grip. The vaccine is prepared by sending a current of air into a specially constructed glass container which reduces the vaccine to the consistency of a mist, which is then inhaled by the patient through a sort of a gas mask tube. The duration of inhalation amounted to from twenty to thirty minutes and the amount of virus vaccine inhaled to from 1.5 to 3 cc. As a rule, one inhalation constituted the sole treatment. A few patients were given two. The patients were divided into equal groups, one being treated with the virus vaccine inhalation, the other, serving as a control, being treated with the usual drugs such as the salicylates, methenamine and calcium. Sixty patients were treated by the inhalation on the first day of the illness and the results were compared with a corresponding group treated with salicylates. Forty-five patients received the inhalation therapy on the second day and a corresponding group was treated medicinally on the second day. A third group consisting of thirty-five patients was treated with inhalation on the third day of the disease and a corresponding group was treated medicinally. The comparison of the results obtained demonstrated the effectiveness of vaccine inhalation therapy in lowering the temperature and in combating symptoms of intoxication characteristic of epidemic grip. The vaccine treatment was particularly effective when applied on the first or second day of the disease. The vaccine when applied during the first two days was likewise effective in aborting the lesions of the mucous surfaces of the nasopharynx and the upper respiratory tract. When administered on the third day of the disease the results were no better than in the control group. The virus vaccine inhalation therapy applied during the first three days of the disease proved to be a valuable prophylactic measure against complications of grip. The author emphasizes a marked diminution in the incidence of pneumonia, otitis, sinusitis and angina as compared with the control group. Recurrences were entirely absent. Of 140 patients treated in the course of 1939 with the vaccine there was not a single instance of pneumonia, whereas there were forty-three instances of pneumonia in the group of 297 cases in a control group. Analogous results were noted during the epidemic of 1938; of 122 cases treated by vaccine inhalation there was not a single instance of pneumonia, whereas there were twenty-six instances of pneumonia among 280 control cases. The virus vaccine inhalation therapy was disappointing in sporadic grip both with regard to the uncomplicated cases and with regard to prevention of complications.

DERMATITIS

CHAIRMAN'S ADDRESS

JOHN G. DOWNING, M.D.
BOSTON

At the turn of the century allergy was an unknown word. It was coined by Pirquet in 1906 to express the concept of an altered capacity to react, in an attempt to simplify the problems of "hyposensitivity and hypersensitivity." Perhaps time will justify its choice, but at present the term needs further clarification. Hence many immunologists and practitioners still prefer such terms as sensitivity, hypersensitivity, hyposensitivity, anaphylaxis and idiosyncrasy. Whatever the fate of the word allergy may be, or the concepts which prompted the origin of the term, it has profoundly stimulated thought, blazed new trails into the hinterlands of research and forged bonds of common interest between dermatology and other branches of medicine, particularly immunology.

Under this influence dermatology has made striking progress in the past four decades. Of special note is our growing knowledge of those groups of so-called eczemas which comprise perhaps three fourths of all cutaneous disease. For a long time the majority held that such disturbances were nutritional in origin. Jadassohn and his school, however, refused to accept this metabolic theory and maintained that most eczemas were caused by external factors. As a result, much has been done to solve the riddle, so much that it would be impossible to give adequate credit to any one individual or group of individuals without slighting some one who also has made a valuable contribution to the solution of the problem of dermatitis and eczema. Therefore, names and references to particular studies will be omitted in this paper, with the understanding that I make no claim for originality but am merely presenting a summary and my opinions based on the recent work for which dermatology owes a debt of gratitude. Investigative research has narrowed the concept of eczema. Narrow as this concept may be, there still remains a group which cannot be explained by external influences.

There have been attempts to eliminate eczema from the medical vocabulary, but like rheumatism it seems entrenched as a household word. To the lay mind it is an awesome and treatment-resistant disease of the skin; to the practitioner it is a convenient label for an

itching cutaneous eruption of doubtful origin, while to the dermatologist it is a symptom complex which at some time in its course is characterized by vesiculation and oozing.

The term eczema may disappear when the causes of all cases are better understood, but it cannot be ignored today. In any case, disagreements over the endogenous or exogenous origin of the disease are of minor importance; the important factor is the research which is simplifying the maze of descriptive morphology by eliminating those cases for which a specific etiology has been found. The essential problem is our understanding of the concepts of specific, altered reactivity or cutaneous hypersensitivity; that eczema, so called, is an abnormal reaction to a normally innocuous exposure and that the person so afflicted has some predisposing change in his system that needs readjustment. By keeping these distinctions clearly in mind, we may be able to control our concepts of allergy and eczema and not let them embrace practically all cutaneous disorders as eczema once did.

Every eczema is a dermatitis but the converse is not true. Dermatitis, a much broader term, is an inflammation of the skin due to internal or external causes, the result of contact, ingestion, inhalation, injection, instillation or other methods of absorption. It is characterized by erythema, edema, papules and vesicles; it may progress to simple scaling and desquamation or it may first become oozing and crusted and then desquamate; it may become secondarily infected with the formation of pustules or persist as an infiltrated, excoriated, lichenified eruption rebellious to treatment. Clinically it may present any one or any combination of the lesions mentioned. Confusion has arisen from the use of the terms eczema and dermatitis as if they were distinct entities. This has been further increased by qualifying the terms according to morphology, topography, etiology and predisposing factors.

DERMATITIS DUE TO EXTERNAL CAUSES

Dermatitis due to external causes (dermatitis venenata) is so common that it requires classification. This classification considers first the type of agent, second the use of that agent and third the nature of the lesions produced. The second division of that classification is of little value because the agent may be employed under continually changing conditions, as for example paraphenylenediamine, which is extensively used in the manufacture of cosmetics, textiles, garments and other branches of industry. The third division is also open to criticism because the same contact may produce varying degrees of disease, depending on its strength as applied, the area to which it is applied and the method of application; that is, friction and the time exposure. As an example I might cite those oils which cause folliculitis of the arms or cancer of the scrotum.

From the dermatology departments of St. Elizabeth's Hospital, Boston City Hospital and Tufts College Medical School.

Because of lack of space this article has been abbreviated in THE JOURNAL. The complete article appears in the author's reprints.

Read before the Section on Dermatology and Syphilology at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

The classification most scientifically accurate is based on the etiologic factor which groups irritants somewhat as in table 1.

In general the concentration of the irritant, the length of time and the conditions under which exposure occurs

Fig. 1.—Dermatitis factitia, July 10, 1934: P. N., a man aged 50, cut the right third finger Sept. 9, 1933. The excrescences resembling dark brown tortoise shell appeared on both hands. Plaster casts ended the lesions and the compensation he was receiving. He was again seen Feb. 13, 1937, when he had an assumed name, similar lesions and compensation from another insurer since April 2, 1936. Casts were not necessary this time; he settled his claim promptly.

serve to differentiate two types of dermatitis venenata—nonsensitization and sensitization. Just where the former ends and the latter begins is often impossible to say. Nonsensitization dermatitis is caused by an irritant that will in given concentrations and under given surrounding factors, such as sealing of the exposed area, affect practically all human skins. Following the repair of such an injury the minutest exposure may suffice to produce a recurrence. Nonsensitization dermatitis is caused by some mechanical or physical agent or by a powerful chemical applied either deliberately or accidentally to the skin. The reaction is sudden and explosive. It is characterized by all degrees of inflammation and at times by the destruction of the cutaneous layers and even the subjacent tissues. The causative factor is almost always recognized and known to the patient; hence recovery is fairly prompt. Conspicuous in this group are the bizarre and unnatural eruptions called dermatitis factitia (fig. 1), which are self inflicted to invoke sympathy, escape unpleasant duties or obtain remuneration. They must be considered in the differential diagnoses of industrial dermatoses.

ECZEMA

Sensitization dermatitis, variously known as eczema, contact dermatitis or contact eczema, allergic dermatitis or allergic eczema, is an inflammation of the skin due to repeated exposures to substances which are normally

innocuous (fig. 2). In this type there is an initial exposure without resulting lesions, but subsequent exposures to even minimal quantities may result in reactions manifested either at the local site of contact or as a generalized process (fig. 3). The disease may be specific or nonspecific and is usually acquired in extra-uterine life.

In occupational eczema this hypersensitivity is obviously so acquired. A review of my last 500 cases showed only one with a positive family history; thirty-three, or 6.6 per cent, showed a previous history of cutaneous eruptions, and of these thirteen, or 2.69 per cent, had been classified as industrial. The development of occupational eczema is usually so gradual that it is

TABLE 1.—Classification of Irritants

2.	Radium and x-rays; radiodermatitis Ultraviolet ray; dermatitis actinica
3.	Mechanical irritation (friction, pricks, cuts); dermatitis traumatica
4.	Mechanical interference with bodily functions (oils or powders); folliculitis
B. Flowering plants and their products—woods, extracts, lacquers; rhus dermatitis	
C. Living agents—fungal flora; dermatophytosis, members of the animal kingdom, mites; dermatitis parasitica	
D. Chemical agents, organic or inorganic; dermatitis industrialis or cosmetica	

difficult to determine when it really began. A sudden onset is rare except when the person has been in contact with a substance for years, followed by a period in which there was no exposure, after which renewed exposure reveals a sudden and severe sensitization. In the typical onset the experienced observer may trace a characteristic development. The areas first affected are those of maximum contact and the initial lesions offer valuable clues. Such lesions occur frequently among seasoned workers. Hence the causative factor is difficult to determine because of the long incubation period (fig. 4). Many occupational dermatitides are true

Fig. 3.—Dermatitis due to adhesive plaster, Oct. 6, 1939, seen on M. C., a woman aged 55. Local and generalized sensitization manifested after strapping of right lower leg.

examples of hypersensitivities. The diagnosis of a sensitization dermatitis is usually obvious to the trained dermatologist; nevertheless a thorough physical examination accompanied by laboratory studies should be made to confirm the diagnosis and determine the predisposing factors.

HISTORY. TAKING

History taking is most important, especially with reference to the time of onset. A careful survey should also be made of the family and personal history in an effort to establish hay fever, eczema, asthma or other manifestations of a family tendency toward hypersensitivities. The patient may state that the eruption has continued for years, while analysis discloses that the attacks are periodic and perhaps seasonal.

In industrial work such a history is most important and its accuracy must be clearly established. Length of service may assist in evaluating the truth of the evidence. The precise time of occurrence is especially significant. An eruption appearing immediately after a vacation would suggest a nonindustrial exposure or an explosive reaction of previously formed hypersensitivity. An eruption appearing at the beginning of a day's work may suggest predisposing home factors such as illness, worry, lack of sleep or dissipation. A similar disturbance at the end of a day's work may indicate excessive fatigue, carelessness or failure to use preventive measures. The introduction of a new chemical should be investigated, as well as the use of sensitizing drugs in the treatment of trivial injuries. From an economic point of view the time of onset may determine which insurer is liable for a disabling dermatitis. Other factors to be considered are a change of domicile, animal pets, plants, new furniture, the use of cleaners or insecticides in the home and recently purchased articles for personal adornment. The history should disclose a picture of the patient's routine and contacts at home, during recreation and at work. A comparison with other members of the family or employees may reveal significant details; otherwise a visit to the home or place of business may be necessary. Such a history will narrow the field of possible irritants and avoid needless cutaneous testing and the invoking of phobias. The history should suggest the cutaneous tests necessary to determine the etiology.

A specific sensitization can usually be discovered, but polysensitization greatly multiplies the difficulties; in a search of the causes of such eczematous dermatitides scratch and passive transfer tests are valueless; patch tests should be employed. A knowledge of closely allied chemicals and the existence of the same chemical in various contacts, in various medicaments and in foods is essential. As an example I might cite iodine in mangoes, cashew nuts and the iodides. The discovery of the etiologic factor and the instructions on its avoidance are the best methods of preventing recurrence.

PROGNOSIS

Prognosis, always important, is especially so with the industrial worker. Here hypersensitivity may be the controlling factor. If this condition is permanent the indisposition will continue. But there are undoubtedly many cases that are aggravated by predisposing factors such as overexposure, carelessness, fatigue, contact with other sensitizers, illness and dissipation. When these factors are removed the hypersensitivity disappears and the patient gets well. A sensitivity may persist although adjusted, but a certain percentage of such sufferers can return to work and remain well. To illustrate:

G. K., a man aged 39, worked for years without a vacation at servicing toilets. He handled a disinfectant containing oil of wintergreen, oil of pine, chlorine and phenol. During his vacation he did odd jobs which involved the use of turpentine and gasoline and on the two last days of his vacation he

suffered an eruption on the fingers of his right hand. This eruption spread rapidly within forty-eight hours after he resumed his regular employment. Drops of turpentine, gasoline and the disinfectant were applied to three areas of the intact skin, blotted and left uncovered. An immediate reaction to the turpentine persisted for twenty-four hours. A few moments later redness was disclosed at the site of the gasoline test; this lasted for six hours. Within a half hour marked erythema appeared at the site of the disinfectant; within twenty-four hours this area assumed the characteristics of his dermatitis and lasted for three weeks.

A thousand questionnaires were recently mailed to workers who had suffered from occupational dermatitis and been discharged as cured more than three years

Fig. 4.—Dermatitis due to nickel, July 16, 1938, seen on E. W., a woman aged 26, a garter maker. Sensitivity to her own garters was manifested on the thighs, later on the hands and forearms, as a result of handling nickel fasteners.

before. The difficulty of conducting a follow-up investigation and the migratory propensities of the lower paid workers were graphically revealed when no fewer than 213 questionnaires were returned because the addressee was unknown or had no address. Replies were obtained from 212 persons, of whom 204 had returned to their occupations. One hundred and four, including eight who never attempted to return to their occupations, suffered no further skin trouble. One hundred and twenty-five were able to remain at their occupations, fifty-five suffering occasional attacks and twelve having continued outbreaks lasting from three to nine years. Eight of these ailing ones were afflicted rather continuously, while in two instances the condition was aggravated by winter and in two by summer weather. If it may be assumed that the 204 replies represent a fair and adequate cross section of the experience, age, physical condition and the like of the 1,000 who were interrogated regarding their experience with dermatitis, it would appear that the average person has almost a

fifty fifty chance of not having a recurrence of his dermatitis if he continues in his same occupation and under the same conditions. However, this assumption may not be a fair one without an analysis of the various exposures of industry. An analysis of the 204 replies with respect to length of service in their present occupation and in relation to the probability of recurrence of their cutaneous disorder revealed a tendency for persons with short periods of service (and thus short periods of exposure) to have proportionately fewer recurrences than those with the comparatively long periods of service. Table 2 may illustrate this point more clearly.

Of those persons having one year of service or less only 13 per cent had recurrences, as compared with 25 per cent who did not. Furthermore, of those having comparatively long periods of service (five years or more) almost one and one-half times as many had recurrences (53 per cent) as did not (36 per cent). Thus it would appear that length of service (length of exposure) has some bearing on the probability of recur-

Fig. 5.—Dermatitis due to strong alkalis, Aug. 29, 1933, seen on G. W. R., a man aged 35, a cloth dyer. Eruption due to caustic soda.

rence of a contact dermatitis. To translate these results into the probabilities of having or not having recurrences of a dermatitis would appear roughly as follows:

1. The chances of the average person who has contracted a dermatitis of having a recurrence, provided he continues at his same occupation and under the same conditions, appear to be about fifty fifty, with the edge slightly in favor of his suffering a recurrence.
2. The chances for recurrence in a person with a comparatively short period of service (short period of exposure), say of one year or less service, appear to be about thirty-five in a hundred.
3. The chances for recurrence in a person with a comparatively long period of service (long period of exposure), say of five years or more service, appear to be about sixty in a hundred.

The apparent tendency for a person to have recurrences dependent on his length of service suggests that sensitization rather than desensitization results from continued industrial exposure. Failure to show clinical symptoms does not suggest immunity or toughening as much as ability to maintain the threshold of resistance. In fact I believe that, if any industrial group exposed

to possible sensitizers is compared with a group not so exposed, skin test reactions would be more numerous among the former group even though they showed no symptoms of disease. The length of service in these cases does not lend support to preemployment patch tests, for ninety-two (90 per cent) of the workers had been employed for from one to twenty years before they showed their first symptoms of dermatitis. In this group of replies no dishwasher or other sufferer from prolonged contact with soap and water returned a questionnaire showing a recurrence. This may be due to the ignorance of this type of worker, but it is unlikely that alkalis (fig. 5) cause a persistent hypersensitivity. The duration of dermatitis from external causes depends on whether it is a nonsensitization or a sensitization eruption. The initial treatment may be a determining factor in either case. However, the former is self limiting, lasting in some instances but a few days and rarely three weeks or more. The latter, when uncomplicated, usually responds to treatment within three months, but unforeseen and unaccountable exacerbations frequently occur. Both may be prolonged by secondary bacterial infection, usually a combination of staphylococci and streptococci.

THE QUESTION OF SECONDARY INFECTIONS

Industrial accident board hearings frequently evoke the statement that mycotic infection has caused the persistence of the dermatitis. Direct microscopic or cultural proof, however, is rarely presented. Two separate investigations for mycotic infections of contact cases that had persisted for more than three months brought out the following results:

At our clinic, where scrapings of the hands and feet of 215 persons with the diagnosis of contact dermatoses were examined by a technician trained in mycologic work, there were 208 negative and only seven (3.3 per cent) positive pathogens, one a trichophyton, and six monilia, only two of which were decided to be *Monilia albicans*. There were numerous molds, yeastlike organisms and bacteria.

In my own office ninety-one cases of occupational dermatitis of the hands which had persisted for three months or more were examined by a mycologist. Scrapings from the hands, feet and other areas of the skin showed, on direct microscopic examination, four positive fungi, three from the feet and one from the hand, while five disclosed mosaic forms. Cultures produced five pathogenic fungi, two trichophytions and two *Monilia albicans* from tissues obtained from the feet and one *Monilia albicans* from the hands. Seventy-six cultures yielded saprophytic fungi of mixed character, while seventy-four yielded bacteria. Eight produced no growth whatever.

The analysis thus disclosed about 1 per cent positive mycotic infection in contact dermatoses. Such figures make an interesting comparison with a similar analysis of persons with apparently normal skin. In 100 such examples in which several areas of skin were scraped and examined, only two were pathogenic, an epidermophyton and a trichophyton, both isolated from the toes. Analyzing these cases, we are justified in drawing the conclusion that a person suffering from a contact dermatitis is no more subject to mycotic infection than one with normal skin. It is my own belief that, when complications arise, the involving organisms are bacterial.

TREATMENT

Treatment depends on whether or not one is dealing with a sensitization dermatitis. The nonsensitive form responds quickly to soothing pastes and lotions. The other type, particularly when prolonged exposure has

occurred, shows a skin so hypersensitive that it reacts unfavorably to medication with pastes or ointments, particularly when they contain mercury, phenol or menthol. Exacerbations arise from environmental exposure. Removing the patient from such exposures by hospitalization and the application of the simplest therapeutic measures such as wet dressings of boric acid or physiologic solution of sodium chloride hasten recovery. As these dressings must be kept continually wet, however, an impossibility in a large hospital, a small private hospital is preferred. Later treatment may include a bland lotion followed by a powder or a stiff paste. This paste should never be applied directly to the skin but should be placed on linen. Too vigorous removal of these applications will delay healing. When there is no apparent bacterial infection it is preferable to leave the lotion or paste on the skin or to sponge it off gently with sterile oil. Ointments are of value in the crusted, fissured or lichenified stage, but roentgen therapy is preferable. The desquamating stage needs no treatment. Vaccines may be helpful in secondary infections with bacteria. Attempts at desensitization, despite the occasional reports of success with plant oils, have

More promising methods are a study of the case history and the administration of a test dose of the suspected drug, which however must be very small, since even a minute amount may induce a severe reaction in a hypersensitive person. Dermatoses caused by hypersensitization must always be differentiated from those caused by overdosage or accumulation. Two illuminating industrial cases due to inhalation are recorded:

R. C., a woman working on suppositories, using lycopodium as a dusting powder, suffered from attacks of sneezing and wheezing accompanied by herpetic lesions on the alae nasi. She gave a positive reaction to the scratch test with the lycopodium.

J. H., a man, handling burlap bags, suffered from sneezing, sore throat, edema of the lids and erythema of the face and neck. He too gave a positive reaction to the scratch test with fibers from a particular type of burlap.

INFANTILE ECZEMA AND DISSEMINATE NEURO-
DERMATITIS

The human skin is becoming increasingly rebellious to the exposures of our so-called civilized manner of living, adornment and diet. In infancy such rebellions are called infantile eczema and may be classified as contact, infectious, metabolic or seborrheic dermatitis, and atopic when there is a family history of hypersensitization. Classification however is quite impossible at this time, for all such eruptions present the same marked erythema and oozing of the face with scattered areas on the body and extremities. Cutaneous tests are of little value owing to the hypersensitive skin of the infant. Family history is valuable in determining the prognosis; that is, when the disease is atopic. Many infantile eczemas clear up before the end of the second year and the patients remain well. Others, however, persist or recur in later childhood or adult life. These tend to become localized in the neck, the flexures and the dorsa of the hands and assume chronic characteristics, papules, fissuring, excoriations and lichenification, arranged in dark grayish plaques. Years may intervene between attacks. Occasionally this type of disease manifests itself first in the late teens. Many dermatologists call this condition disseminated neurodermatitis; others, atopic dermatitis. I myself prefer the former term, although the latter may be used when there is a positive family history of hypersensitivity. These cases show an eosinophilia, specific circulating antibodies or reagins (not precipitins) demonstrable by passive transfer, and positive intracutaneous and usually negative patch tests. The antigens are mostly protein. White dermatographia may be elicited by stroking the skin. As to etiology, however, the literature is full of contradiction (fig. 6).

A psychogenic origin is advanced by some observers and decried by others; a positive family history of hypersensitivities is reported in about half of these cases. Some investigators find these patients highly intelligent while others record them as of average or below average mentality. Some find seasonal exacerbations worse in summer, while others blame winter climates. Foods, particularly fish and eggs, are accused, as is silk and wool clothing. While I do not credit a psychogenic origin for such disorders, it has been my experience that most patients were fairly intelligent, some extremely so, that less than 20 per cent have a positive family history, that attacks were more pronounced in winter and that acute exacerbations might be induced by worries or mental and emotional upsets.

not proved of value. They should be used cautiously, for they may cause severe reactions; this is true also as regards prophylaxis. Conflicting reports are published regarding even the value of Rhus toxicodendron. Antibodies have not yet been demonstrated in cases of contact dermatitis, but more delicate methods may yet reveal their presence.

DERMATITIS DUE TO INTERNAL CAUSES

In cases of dermatitis from internal causes, drugs are the main factor causing dermatitis medicamentosa through ingestion, injection, absorption or inhalation. Antibodies have not been demonstrated in drug eruptions. These eruptions are prevalent, for almost any drug may cause a reaction in a susceptible person. In fact, the sudden appearance of any eruption without a systemic disturbance suggests a drug as a possible causative agent. Such eruptions are symmetrical and pruritic and may assume any type or combination of the primary lesions. An interesting group is that of fixed eruptions which do not suggest permanence but tend to reappear at the same site. These are vascular and polychromatic in appearance and are occasionally accompanied by vesicles and bullae. I have seen one case of a generalized bullous eruption in which an area of necrosis on the lower right leg was produced by too large a test dose of phenolphthalein. Cutaneous tests have not proved their value in drug eruptions except in eczematous groups, where patch testing is useful.

Testing at such times, by increasing emotional strain, may well invite disaster. In hospitals, with a house diet and lying on an old mattress, the patient may find relief. A shrewd evaluation of the factor which brought on the attack, questioning on financial and domestic worries and dietary, social and occupational habits may suggest future therapy and certain beneficial tests. In one case an inhalation test with silk in an allergen-free room produced a brilliant cure. However, investigation usually reveals polysensitivity so that the elimination of any one factor rarely brings complete relief. Hospitalization, therefore, does not produce a cure. Such patients recover temporarily but fail to cope with their environment, mental and social, and suffer recurrences until maturity and intelligent self adjustment bring a cure. Credit then commonly goes to the attending physician or to the elimination of such substances as eggs from the diet or silk from the wardrobe. Cases of neurodermatitis disseminata are rarely seen in persons of middle age. Persistent contact dermatitis may present all the clinical characteristics of neurodermatitis. History taking and patch tests, however, aid in making the differential diagnosis. Cutaneous tests are likely to yield conflicting evidence. Negative tests, when the patient is known to be hypersensitive to a given substance, are difficult to explain. The reverse is also puzzling—a positive test without clinical symptoms. Moreover, a test which is positive one day may be negative on another, or vice versa. An explosive reaction may follow the mere ingestion of or contact with a causal factor, while later a similar exposure may prove innocuous. Many factors doubtless contribute to this confusing situation; overexposure to a given substance, fatigue, worry, emotional upsets, intercurrent infection or some systemic disease. Hence both the predisposing and the precipitating causes must be sought, and both may be internal or external.

PATCH TESTS

Patch tests in dermatology are more effective than scratch or intradermal tests. The patch test is based on the principle of specific altered reactivity or hypersensitivity. If a patient exhibits an eczematous dermatitis as the result of hypersensitivity to a given substance, the entire skin becomes sensitized. When this substance is then applied to an intact area of the skin in a manner similar to the initial exposure, a reaction comparable to the original eruption should appear on the test site. How this generalized sensitization is produced is still a matter of conjecture; whether it is spread by means of the blood or lymph or in the skin from one epithelial cell to another. Any dermatologist familiar with a large series of contact dermatitides is at a loss when he attempts to satisfy himself that they are spread by epidermal extension.

In patch tests it is important to duplicate, so far as possible, the original exposure. A list of primary irritants must be established. If a worker comes in contact with a primary irritant during his labors or elsewhere, patch tests are needless. If they are also sensitizers, destructive action may result at the test site, and a generalized dermatitis may follow; for example, oil of cinnamon and oil of cashew nut shell. Tests with stock solutions may suggest possible clues but cannot be accepted as proofs.

Experience teaches discretion. Such tests are rapidly assuming unexpected and unwarranted legal impor-

tance. A court has recently been questioned as to medical practice which failed to apply patch tests. A physician can testify only to results of tests that he himself applied. Whether the test substance was the one which caused the trouble or merely resembled it may be brought into controversy. Tests with stock solutions are inadmissible as evidence. The commissioner at the industrial accident board recently ruled out my opinion because I could not recall whether the insurer or the patient had brought test materials to my office the previous year.

Tests, when corroborated by clinical data, are of value. Cure or renewed attacks should follow elimination or reexposure to the proved irritant. A positive reaction after a week's interval is usually a sensitivity produced by the test itself. Reactions from rubber and dyes are likely to be delayed. After tests have been applied to the skin, the patient should remain under observation for at least an hour; the sites should be examined before dismissal and, if negative, be replaced for from twenty-four to forty-eight hours. The area tested should be examined for several days. An industrial physician in a recent article stated that during preemployment examination he made patch tests with phenol formaldehyde resins in which he "superficially scarified the skin and many of the new workers were found to be hypersensitive, showing a reaction immediately or within twenty-four hours." Evidently the patch test is not yet clearly understood. The skin should never be traumatized before or during the application of test substances but should always remain intact.

PREVENTION

Prevention can be accomplished by education. Public talks to the laity, to employers and to workers are of value. Contacts such as poisonous chemicals and plants should be explained. Few persons are immune to irritants. At our clinic twenty-three paid volunteers allowed poison ivy leaves to be rubbed on their unabraded skins, which were then covered with sterile gauze. Twenty reacted positively in from one to eighteen days, with varying degrees of dermatitis. One subject showed a generalized eruption from this single contact. The public should be taught that drugs are common sensitizers and should become sensitivity conscious. If a dermatitis appears after the use of any drug, that drug should be suspected and eliminated and another drug of equal value substituted in its place. For example:

An intramuscular injection of estradiol benzoate was followed by an area of erythema, edema and pruritus at the site of the injection; this was about 3 inches in diameter. This persisted for about three weeks. The same type of estrogenic substance in a different vehicle was injected with no further trouble.

This prevented an extensive dermatitis such as was reported from repeated injections of theelin, in which case each injection caused an extension of the existing eruption.

Many disasters have been prevented in the past thirty-five years by the Council on Pharmacy and Chemistry of the American Medical Association. As a result of the federal drug and cosmetic act the public is becoming educated to the risk inherent in the use of certain drugs. The Food and Drug Administration has already attempted to prevent the sale of certain drugs without a doctor's prescription. Warning state-

ments are placed on the labels, for example "If a skin rash appears, discontinue use." Reliable drug houses have shown an encouraging spirit of cooperation by discountenancing the indiscriminate sale of dangerous products. In fact the entire industry seems conscious of the advisability of ethical marketing. When the manufacturers of cosmetics also disclose by labels the main ingredients of their products, persons with known sensitivities can avoid possible causes of dermatitis. Labeling is important also in industry, particularly for volatile solvents, essential oils and irritating chemicals. If such substances cannot be eliminated entirely, workers should be instructed and preventive measures instituted. If a drug such as mercury is to be applied to the skin, the patient should be advised to test himself prior to its extensive use.

Case reports are continually augmenting our knowledge of irritants and sensitizers and should prove their value in avoiding cutaneous disorders. However, a useful drug need not be banned because of the risk of a dermatitis when that risk is outweighed by the curative properties of the drug in question. Among such drugs are the arsphenamines, sulfanilamide, the iodides and the bromides. After initial disturbances a patient may become more tolerant of a remedy so that its use can be resumed with corresponding advantage. What is true in the case of an individual drug is true of industry. With proper care and observation a sufferer from industrial dermatitis may learn to adjust himself to conditions that seem decidedly unfavorable. Such experiences are common among bakelite molders, treers and bakers. Proper hygiene, both personal and industrial, is and will remain paramount.

CONCLUSION

Eczema, a symptom complex, denotes a dermatitis caused by a normally innocuous exposure which in most cases has been proved to be external in origin. The term allergy may be accepted according to the definition of a specific altered capacity to react, if the causative factors can be specified, as in the case of bacterial infections. The statement that a patient has an allergic dermatitis or eczema is of no value; it must be demonstrated that the patient with the dermatitis has a specific altered capacity to react, or cutaneous hypersensitivity, to a specific exposure or exposures. The fact that a certain percentage of persons who have suffered from contact dermatoses can readjust themselves to previously harmful exposures would indicate that they have no permanent abnormality as a result of their previous hypersensitivity.

520 Commonwealth Avenue.

The Ordinary Everyday Things.—All mothers frustrate their children, but the mother of the sort I am describing, having no sympathy or patience, increases the inevitable frustration a hundred or thousand fold. Instead of sympathizing with the jealous child she is angry, instead of comforting him when he is miserable she gives him a slap, instead of joining in his play she puts him to bed, instead of taking part in his phantasy life she accuses him of lying. It is not that she uses any particular form of punishment or indulges any special cruelty. It is not that she says or does anything very terrible; but the way in which she does and says the ordinary everyday things of life is what seems to damage the child. When he is treated in this way, it seems to me small wonder that the child develops a greater degree of rage, jealousy and libidinal demand than the average.—Bowley, John: *The Influence of Early Environment in the Development of Neurosis and Neurotic Character*, *Internat. J. Psycho-Analysis* 21:154 (April) 1940.

PRESENT TRENDS OF SOCIALIZATION OF MEDICINE IN RELATION TO MATERNAL WELFARE

CHAIRMAN'S ADDRESS

LUDWIG A. EMGE, M.D.

SAN FRANCISCO

The complications of modern medical practice resulting from our economic upheavals demand immediate and momentous changes in our professional attitudes. We are confronted with new problems and new ideas which call for a complete change in our ideals. We are told that individualism in our field no longer has a place and that we must organize our forces and prepare for a new tempo in the distribution of medical care. Numerous plans have been drawn and at this particular moment are being tested for the solution of the perplexing health problems arising from the economic changes of the past two decades.

Our particular concern in these plans is maternal and child welfare, which is in dire need of improvement. We have been told time and again that the maternal risk in this country is too high and that better methods must be devised to correct it. Various surveys have shown that the risk is greatest among those who are financially handicapped, and attempts at improvement by various isolated groups during the past twenty-five years have demonstrated that much can be accomplished through group action toward the establishment of maternity centers and educational campaigns. The splendid efforts on the part of the Children's Bureau in Washington to support these commendable movements and provide facilities is well known. The sum total of the experiences of the various groups directed toward the reduction of maternal risk has proved that the results depend entirely on cooperation, efficient organization and adequate funds.

By and large, medical practitioners are individualists and, by tradition, isolationists. Group effort to many means the surrender of these ideals, although there is no proof for this contention. In fact, group action means nothing more than the intelligent coordination of individual efforts. Now, more than ever, is individual effort needed to lower the hazards of childbirth, for they have become the concern of the nation. It is evident that to achieve this the adoption of some plan along the lines of socialization is necessary.

AIM OF SOCIALIZATION

Under the influence of democratic principles and ideals, socialization has come to mean economic preservation and efficiency. Industries are applying its principle in an ever widening scope, and constituted authority has adopted it as the only means of handling the problems created through economic chaos. In the broader sense, socialization aims at the economic betterment of society, and our profession should accept it in that light. If instituted in an orderly and sane fashion to conform with major changes in our modes of living, it is a step forward toward a less complicated community life. All schemes of socialization are predicated on taxable resources or on insurance (compulsory or voluntary). That we interest ourselves in the mechanism of socialization in the field of medicine, therefore, is only common sense and a step in the right direction for our

Read before the Section on Obstetrics and Gynecology at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

own protection. The application of social principles to medical practice is not new. It has been used in one form or another for many years, particularly as it relates to maternal and child welfare.

Originally a problem handled entirely by teaching clinics and philanthropic institutions, this particular field of welfare work gradually has been entered by municipalities, then by counties, later by states, and most recently by the federal government. All will remember the Sheppard-Towner bill and how it was opposed because it was considered the first step toward control of medical practice by the government. Time proved it otherwise, and had it not been for financial limitations and lack of trained workers the results might have been different. The bill was introduced at a time when economic affluence made maternal needs less evident. The economic collapse of the last decade put it to a strain it was not prepared to endure.

The Sheppard-Towner Act was superseded in 1935 by the Social Security Act, which broadened its scope and permitted the Children's Bureau of the Department of Labor and its affiliated state agencies to improve field nursing, increase the number of maternity and child welfare centers and embark on a more extensive educational campaign. It is evident that it has borne fruit, as witnessed by the steady, though slow, improvement in maternal risk.

NATIONAL HEALTH PROGRAM

The federal government now proposes to enter the field of maternal and child welfare on a still larger scale because of pressure from interested nonmedical groups representing that great proportion of our population unable to obtain low cost medical attention, and because organized medicine is said to have been too slow in improving maternal risk. It is planned to spend for this purpose eight million dollars the first year, twenty the second and thirty-five the third, to be followed by such sums as Congress deems necessary to maintain adequate care for expectant mothers and their offspring. This provision is incorporated in a bill (S. 1620) introduced by Senator Wagner to establish a National Health Program. It has been heard in committee, and a copy of the record is readily obtainable. Those who care to know the opinions of leaders in medicine, labor, economics, farming and various industries concerning the distribution of medical care in general, and maternal and child welfare in particular, should read a copy of these hearings. They are very informative and reflect the needs and demands of the people. I recommend also that they study the proceedings of the National Health Conference and the Conference on Better Care for Mothers and Babies held in Washington, D. C., in 1938. It will enable one to compare the opinions of one's colleagues with those who are clamoring for improvement in medical service. Physicians should be conversant with both in order to meet public challenges.

Briefly, the proposed legislation is designed to permit the states to render increased service to pregnant women and to children through grants-in-aid. It is meant particularly for the improvement of rural conditions and for areas suffering from severe economic distress. This bill authorizes the chief of the Children's Bureau in Washington to determine the financial needs of the various states and allot to them sums of money based on the total number of births in the preceding fiscal year and on other health needs of mothers and children as estimated by state authorities. The proposed legislation differs from the Social Security Act in that it

eliminates the fifty-fifty participation by the states in the provision of necessary funds and proposes to contribute grants ranging from 33⅓ to 66⅔ per cent of the total amounts to be expended under state plans. It is evident, under the Social Security Act of 1935, that states suffering most severely from economic depression, and hence limited in taxable resources, did not receive as much federal support as needed and that states better able to finance their own maternal welfare programs received more than necessary. While there is an improvement over the Social Security Act, it still fails to take into consideration the fact that certain local needs cannot be measured in terms of finances and therefore it may fail to solve some of the pressing medical requirements of such regions. This section of the bill obviously needs revision.

There are incorporated into this bill certain restrictions and administrative rules which make the chief of the Children's Bureau, under the Secretary of Labor, the sole judge in all matters pertaining to the fulfillment of this legislation. It is evident that such a concentration of power may become a dangerous factor. A far-sighted chief, such as the present one, probably would consult with the medical profession regarding needs and methods best suited for a given region. A more arbitrary and politically inclined person, on the other hand, might impose measures which easily could prove obnoxious to the practitioners and thereby defeat the spirit of the bill. I wonder if physicians realize that the distribution of funds for medical care is essentially in the hands of social agencies. This may be an administrative expedient, but it puts physicians in the back seat. We should be at the wheel, and we can be if we insist that all federal medical matters be concentrated in a Department of National Health, as emphasized in the Platform of our Association.

CARE OF MIGRATORY WORKERS IN CALIFORNIA

Until a few years ago, medical practitioners managed very well on their own, and their willingness to care for the sick without material reward was recognized throughout the country. Our present economic situations, however, are changing, and even our contribution of a million dollars or more a day in professional service does not solve the urgent medical needs of certain sections. Take, for instance, our recent experience in California. For several years many thousand disconsolate, underfed and destitute migratory workers poured into the state in a steady stream. Who was to care for their pregnant women and their sick children? Was it up to the nearest local physician or was it the duty of local health authorities to provide adequate and decent care? Or was this a federal responsibility? In many instances the brunt was borne by the local doctor until the problem got beyond him. Regardless of what has been said in sordid fiction, I know from personal investigation that many members of our profession and local health departments did their level best under the circumstances, but it was not adequate. To achieve the desired end, forces had to combine. Improvement came when state, federal and medical forces joined hands to provide means and facilities for relief of the suffering. Today, mobile clinic units follow the workers to the crops, stationary maternity centers manned by part-time physicians and dentists have been established in convenient localities, and every migratory pregnant woman in the state has access to adequate care. Sometimes superstition or ignorance keeps a woman from making use of the facilities offered, but we cannot help that.

Last year 2,259 of 2,932 migratory women were delivered in hospitals, a considerably higher proportion than is true of most rural districts in the nation. This demonstrates what efficient organization and group effort can achieve, and it demonstrates at the same time that the individual physician could not cope with such events. Like emergencies may arise in any state and, while they are primarily the concern of health departments, our profession is bound to be drafted. So why not organize and be prepared?

IMPROVEMENT IN MATERNAL MORTALITY

There is another phase of the maternal welfare problem which I believe can be solved only through some form of medical socialization, and that is the present state of our maternal mortality. All are familiar with maternal risks in the United States as compared with those in other countries. It long has been a subject of concern to most of us and has given us a black eye before the public. What are we going to do about this? Shall we organize and strike at the root of the evil, as a few isolated groups have done, or do we want the government to do it for us? If we expect to assume the leadership in this matter we must prepare ourselves to set aside certain archaic ideas of ethics for the sake of eliminating the incompetent. If we want to be led, then the public, through the federal government, will tell us who can and who cannot attend women in childbirth. Remember the reports on maternal mortality by various interested groups and the impressions they created, not only in their respective communities but throughout the country! There was a great deal of criticism within the profession over these reports, but they did have a salutary effect. They awakened many doctors to the necessity of increasing their efficiency through graduate study, and they stirred up various health agencies to foster better maternal care. Call these efforts at improvement what you please; in the final analysis they are a form of socialization, since they are concerned with group action for the benefit of society.

To show where there is the greatest need for improvement, I have prepared a table of maternal mortality rates supplied by the Children's Bureau of the United States Department of Labor. It is arranged according to the number of deaths per state in 1938 as compared to 1936. The table speaks for itself; each should make one's own deductions.

Let me say in passing that the Negro population of all states has a higher mortality rate than the white population. This, no doubt, explains the alarmingly high maternal mortality rates in certain Southern regions where the proportion of Negro births is highest. Negro births in the Southern states fall for the most part into rural districts and are accompanied by a far greater mortality than in the Northern states, where the colored population concentrates in towns and cities. The situation evidently will have to be remedied through some social scheme sponsored by constituted authority and made effective through medical cooperation. If the number of Negro physicians and public health nurses is not sufficient to cope with the problem, then some other way will have to be devised, preferably through a combination of public health forces and county medical societies.

As a matter of record I wish to point out that, notwithstanding recent statements made at health conferences and hearings, maternal risk in general is decreasing steadily and maternal mortality rates have improved universally. I am certain that medical group

efforts, educational campaigns fostered by teaching institutions, the Children's Bureau, medical societies, numerous state welfare agencies and the American Committee on Maternal Welfare have contributed immeasurably to this achievement. The development of obstetric graduate study is the next step to improve the situation further. It too is a cooperative effort and a phase of socialization, since it aims to improve medical practice for the amelioration of the health of the public.

HOSPITALIZATION

There are many other phases in the care of the pregnant woman which cannot be solved except through some social scheme. Take, for instance, hospitalization. Today it costs roughly from \$5.50 to \$6.50 a day to house, feed, nurse and deliver a patient and take care of the baby on the basis of a ten day hospital stay, with an additional dollar or two a day if a physician-anesthetist is employed. It is evident that this puts hospitalization beyond the reach of a very large proportion of our pregnant women. This phase of the

problem cannot be solved by philanthropic aid or by the present setup of county hospitals, many of which hardly deserve that designation. Today even those of moderate incomes often cannot afford adequate hospital care unless it is provided through hospital insurance. However, since it is more expensive to hospitalize maternity patients than others, voluntary insurance groups are slow to include this service in their policies. It will take some time to learn whether, under the present rates and restrictions, this service ultimately can be provided. In the meantime, from 20 to 70 per cent of our expectant mothers, depending on whether they are living in urban or rural districts, are forced to have their babies at home. If it is to be the ultimate national aim to have all babies born in hospitals, the financial burden must be borne by constituted authority through some means of taxation. That this requires the setting up of some social mechanism needs no comment. Certain of our lawmakers contemplate the institution of a nationwide hospital building program which, I fear, in the proposed form is not entirely based on necessity. I cannot go into the details. They can be read in a bill (S. 3230) known as the Wagner-George Hospital Construction Bill, which recently was discussed in THE JOURNAL. It is a very ambitious and

expensive scheme of socialization which throws the ultimate maintenance cost onto the community and still does not solve the individual hospitalization cost, although it is claimed that this would be achieved through funds provided by the National Health Act. I am unaccustomed to large figures and cost sheets, but I can see that even the sums set up by that act would not nearly cover the cost of hospitalization of expectant mothers now delivered at home, to say nothing of compensating the attending physician. If the federal and state governments want to increase maternity hospitalization they could do so by adding to or subsidizing present facilities with a tremendous saving in capital investment and in administrative cost. Here again cooperation and solidarity in the medical profession can play an important role. An equitable and satisfactory distribution of the burden of the cost of hospitalization for that large group now not eligible or not able to afford it can come only through a plan of socialization, and our profession can show the way to the most economic solution of this problem.

Time does not permit the discussion of many of the interesting details which enter into social schemes connected with maternal welfare. The question of compensation for adequate maternal care I leave out purposely, because it cannot be answered without considerably more experience and study. However, this phase will have to be watched for the tendency is to put the valuation of maternal care at the end of the list.

POSITION OF PHYSICIANS IN ADMINISTRATION

We are charged with the responsibility of watching over the welfare of mothers and babies and we should let it be known that we want a hand, not only in their practical care, but in administrative matters concerned with the distribution of funds for such purposes. It is high time that the profession make itself heard, and it is to the interest of every practitioner to lend a hand. I feel very strongly that this subject must be brought out into the open so that the people with whose care we are charged can learn our ideas regarding national health programs. If we ever want to be heard, we must raise our voices now, and when we do, we must speak with conviction and be prepared with practical suggestions. Health legislation affects you and me vitally, and, since it is evident that the health needs of certain groups can be supplied only through some governmental subsidy, by all means participate in the shaping and enforcement of such legislation. Do not relinquish leadership in medical matters, for by nature of your training and experience you are best prepared to lead in that field. Above all, remember that the burden of maternal mortality rests on our shoulders, so why not make a serious, united effort to lighten that burden? A little more cooperation, a little more frankness and a lot of good will would go far in achieving this for us. Prove to your community that it must provide better facilities for its expectant mothers and aid in the establishment of maternal and child health centers. Create study groups and discuss your problems together, and invite particularly proficient practitioners to discuss them with you. What has been done to improve maternal risks in the large centers may be accomplished in the smaller communities and rural districts if your respective county societies will determine the causes of deaths in childbirth in your own localities and study the existing facilities for maternal care. This will require an effort, and some feelings may be hurt, but why not look at it in the spirit

of service? Individualism need not be lost. Many of you belong to civic societies and you take pride in being of service to your fellow men. Has not medicine ever been dedicated to service? The time has come for all of us to apply this principle to changing needs, but it cannot be done by merely quibbling over the philosophy of social trends; it requires action—organization and cooperation—and this must come from within our ranks.

2000 Van Ness Avenue.

INJURIES OF THE KIDNEY

WITH SPECIAL REFERENCE TO EARLY AND
ACCURATE DIAGNOSIS THROUGH
PYELOGRAPHY

JAMES C. SARGENT, M.D.

MILWAUKEE

What with modern high powered automobiles and the ever lengthening superhighways of America, there is a sickening tide of broken and torn bodies streaming steadily into the admitting wards of our emergency hospitals everywhere. With a public still sadly indifferent to the horror of this mounting holocaust, a responsibility of particular weight rests on the profession to whose lot it falls to comfort and to heal. While those of us committed to the practice of urology find ourselves involved in this mess perhaps less frequently than our friends the orthopedists or the general surgeons, present day accident surgery is freighted with perplexing urologic problems sufficiently common and of such wide variety as to command our most thoughtful attention.

Not alone have recent years brought an astounding increase in the number of cases of injury involving the organs of the urinary tract but at the same time they have brought such astonishing changes in their type and degree that several new questions of major significance have risen to plague us. Not the least of these—and I venture here to inject perhaps the most confusing and unanswered of them all—is that of the safest and best methods to be used in the early recognition and the precise classification of kidney injuries. It is to this particular phase of accident surgery that this paper is addressed.

To any one called on to serve as consulting urologist on the staff of a sizable emergency hospital, it must soon become apparent that the mine run of urinary tract injuries are quite symptomless and obscure on admission. Indeed, so obvious and commanding are the symptoms of the other accompanying injuries and so silent those of the kidney or bladder that important hours are often lost unless the prompt discovery of kidney or bladder injuries is assured through the routine inspection of the urine to note the presence or absence of blood in all accident cases at the time of admittance. Without such a routine, the patient with a fractured pelvis may go many hours before her ruptured bladder is discovered or the man unconscious from skull fracture even bleed to death from an unsuspected kidney injury.

Striking too is the observation that frank hematuria can be noted in bad accident cases and yet the most painstaking search fail to reveal any demonstrable urinary tract injury and a few days see the urine again clear and the patient apparently none the worse for

Read before the Section on Urology at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

the wear. Particularly is this likely to occur in those accidents in which bodies have been jarred violently by falling, by being slammed against a tree while coasting or in a head on collision with another car. Along with punctured lungs, broken limbs and skull fractures, a sizable number of these heavy body injuries are found to show grossly bloody urine perhaps clearing completely within a day or two but eloquent evidence of the fact that the renal tissue of a kidney is too soft and friable to be slapped against the lumbar spine without likelihood of some degree of injury.

Injuries of the urethra and of the bladder are so classic in their method of occurrence and they are associated with such characteristic local effects that any reasonable investigation is bound to lead to their prompt discovery and, once discovered, their treatment is quite routine. The trouble does not lie there.

Rather, the real problem in injuries of the urinary tract lies in that group of cases in which the kidney has been hurt. And the reasons are not hard to find. Here, unlike injuries lower down the tract, there is not the likelihood of urinary extravasation to make immediate surgical intervention imperative. Here hemorrhage alone is a danger and then only in the most occasional of cases. Here surgical intervention is a formidable procedure and altogether too risky to be undertaken without real cause. Here, as a matter of fact, experience teaches that the vast majority of injuries are far better left alone. Indeed, the problem is not so much that of detecting the presence of kidney injury as it

Even perirenal extravasation of urine with the likelihood of later abscess can demand consideration. Completely overshadowing them all, however, stands the paramount question How badly is the kidney hurt? Is it fragmented and macerated beyond hope of spontaneous repair? Or are its bruises and tears within

Fig. 2.—The contour of the renal pelvis is completely lost. The kidney was found fractured beyond possible repair.

Fig. 1.—The contour of the renal pelvis is well preserved despite subcapsular fracture of the renal cortex.

is of knowing the exact extent of the injury and whether or not operation can safely be avoided.

In approaching the answer to this question there is nothing whatever that ranks with a clear understanding of the exact extent and severity of the kidney injury itself. Of course severe shock when present may be of outstanding significance. Signs of progressive hemorrhage may be quite commanding. Injuries elsewhere in the body may tend to dominate the whole procedure.

the bounds of good healing if merely left alone? On the answer to that question, more than anything else, rests intelligent judgment as to proper treatment when kidney injury has occurred.

Two cases are submitted in illustration of this point:

A middle aged man who had been bowled off his feet two hours before by an automobile entered the hospital in moderate shock. Urine obtained by catheter was found to be quite bloody. Rapidly increasing pain and rigidity suggested left kidney injury and careful urologic studies were made (fig. 1). It was perfectly obvious from this retrograde pyelogram that frank fracture of the left kidney had occurred. But it was also obvious that the kidney and its true pelvis were sufficiently intact to promise good healing. After eight days of bed rest the patient saw so little excuse for his hospitalization that he signed his own release and left. Urologic studies made in connection with litigation the following year demonstrated this kidney to be functionally and anatomically indistinguishable from its uninjured mate.

A grown girl too drunk the night before to know how she had been hurt came to the hospital about noon frightened over her bloody urine. Nor, oddly enough, was there a bruise or a scratch on her body to hint the presence of her injury. A growing dull ache over her left kidney suggested that it might be the source of her bleeding. Cystoscopy showed blood rolling from the left ureteral orifice. This retrograde pyelogram disclosed complete loss of continuity of the renal pelvis and indicated that the kidney to be injured beyond possible repair (fig. 2). Her general condition remained quite good and operation seemed both safe and wise. The kidney was found broken completely in two with an upper and lower half dangling loosely in a quart of clotting blood, one anchored by a few viable shreds of pelvic mucosa and the other by the skinned renal artery and vein.

Several authors have written, praising intravenous urography in the study of renal injuries and calling

particular attention to its simplicity and complete safety. Be all of that as it may, there is much to question its worth except, perhaps, as the roughest sort of a preliminary survey in those accident cases in which the urinary tract is suspected. Most intravenous urograms made on patients just admitted after serious accident

Fig. 3.—The intravenous urogram showed no elimination of the drug by the injured kidney. Yet the left pyelogram proved the kidney to be quite intact.

are, in my experience, quite valueless. If the patient is seriously hurt he is likely to be in shock, and shock is a poor circumstance in which to expect even uninjured kidneys to do a reasonable job in eliminating the drug in sufficient concentration for good pyelographic detail. Ileus, more or less severe, is also quite common and adds to the difficulty of getting clearcut, distinguishable outlines of the pelvis and calices.

Entirely apart from these general considerations, the intravenous urogram finds serious limitation in the fact that, far more often than not, a kidney stops secreting urine promptly on receipt of injury, whether that injury is one of simple concussion or of a severe shattering of its parenchyma. Not only does this usually leave the surgeon without the information he so seriously needs, but by what appears to be complete absence of function it may give an impression of kidney damage thoroughly false and gravely misleading.

In support of this contention I submit a twenty minute intravenous urogram, together with the left half of a retrograde pyelogram (fig. 3), both of which were made quite soon after the patient's admission. The case was one in which the type of violence and the severity of symptoms suggested the likelihood of serious left kidney injury. While the right kidney was well visualized in this intravenous urogram, on the left side nothing but a faint streaking of dye in the kidney region could be seen. Had this intravenous urogram been taken at face value, one would have expected to find the left kidney badly damaged. Yet the retrograde pyelogram proved the kidney completely intact except for an insignificant medullary tear and several days of bed rest saw the patient well and home again.

Retrograde pyelography, done on a proper x-ray table and with a Bucky diaphragm, must come to be routine in all accident cases in which injury to the kidney is suspected. I would take issue even with those who point to the supposed hazards of such a bold regimen. Using the newer drugs and with sterile

technic, no serious harm can possibly come from retrograde pyelography—certainly nothing to equal the danger of case management without it. A good retrograde pyelogram will prove beyond reasonable doubt whether or not renal injury has occurred. Of vastly greater importance, however, it will usually show if the parenchyma and the pelvis have been shattered beyond all possible hope of decent healing. With the contour of the renal pelvis reasonably well preserved, even though frank rupture of the parenchyma may be quite evident, one does not expect serious consequences to ensue and a masterful indifference on the surgeon's part is quite likely to see the patient and his kidney both whole and well again. Conversely, if the pyelogram shows the continuity of the pelvic cavity blasted beyond recognition, there can be no hope whatever for the kidney and but little for the patient unless a propitious time for nephrectomy can be found.

Two cases have been chosen to illustrate the truth of these observations:

A young man who had tumbled down through six floors of scaffolding suffered nine more or less serious bone fractures along with lesser injuries. He entered the hospital in profound shock and was unconscious from severe brain concussion. After several hours of supportive treatment he rallied sufficiently to permit a thorough study of his injuries. The catheterized urine was thick with blood. Severe pain and boardlike rigidity soon settled over the entire left side and back. Cystoscopy showed blood running from the left ureteral orifice. The retrograde pyelogram (fig. 4) gave eloquent proof of the presence—and incidentally the relative inconsequence—of his renal injury. Particularly one should note the unbroken contour of the entire pelvis and its three main branches while the fog of pyelographic solution floating between upper and middle calix demonstrates the location and limited extent of the parenchymal fracture. This patient was months in the hospital following his accident, but except for his bone injuries he might well have been out and at work within the week.

A daughter just reaching womanhood had the misfortune to be shot in the back by her degenerate father. The bullet

Fig. 4.—Retrograde pyelography proved the kidney pelvis completely intact. A small fracture of the renal cortex may be seen spreading between the upper and middle calix.

entered at the left of the upper lumbar spine, emerging high in the left axilla. On admission her clothes were noted heavily blood stained but there was no indication of alarming hemorrhage. She was neither in shock nor in material pain. However, as hours wore on her pulse began to quicken. Pain, tenderness and rigidity localized in the left hypochondrium. Distention and vomiting appeared and increased steadily. Indeed, all signs seemed more and more to point to an abdominal

injury—that is, all except the heavy bloody discoloration of the urine. A retrograde pyelogram (fig. 5) was promptly made, whereupon it became evident that the left kidney had been caught by the bullet in flight and that severe damage had occurred. Indeed, the film seemed to indicate all but the extreme upper pole of the kidney to have been shot completely away. True to this prediction, operation disclosed a quite normal upper pole with the rest of the organ pulverized beyond recognition. With this kidney remnant removed and two small wounds in the large bowel located and closed, we hoped that we had spared her life. But the paths of bullets are notoriously weird and devilish, and a coroner's inquest came along in due time to enlighten and deflate us. Through all our error and

mits quite exact interpretation and even then if substantial injury seems to be present.

4. Finally, I would reiterate my firm belief that it is in the retrograde pyelogram—and there only—that one can find substantial, dependable and consistent help in determining when and when not to operate on a kidney that has been injured.

324 East Wisconsin Avenue.

ABSTRACT OF DISCUSSION

DR. ROY B. HENLINE, New York: Dr. Sargent's discussion of renal injury has stressed the value of retrograde pyelography in suspected renal injury. Such a procedure, done under sterile precautions, should afford more accurate information regarding the extent of the renal damage. Using the newer contrast mediums for pyelography, which may readily and harmlessly diffuse with the blood, should add no additional hazard to a patient with a ruptured kidney. One has no reason to regret the performance of retrograde pyelography in these cases, and in several instances more precise information regarding the condition of the kidney has been obtained than was possible by excretory urography. Too many general physicians rely on the erroneous information often obtained from excretory urography. However, many such injuries can be diagnosed by excretory urography alone. Stirling reports a satisfactory diagnosis in twenty-three of thirty-four patients with ruptured kidney by excretory urography. One should not hesitate to perform a retrograde pyelogram in any instance in which the diagnosis and extent of the injury are in doubt or in which the kidney or renal pelvis is not well outlined by an excretion urogram. Many cases reported as ruptured kidneys are merely contusions and require bed rest and supportive measures but no surgical intervention. A true rupture of the kidney, resulting in gross injury to the pelvis, cortex or capsule, represents serious renal damage. These patients should be operated on as soon as the diagnosis is made, provided shock and other injuries will permit. To postpone surgery in these operable cases is poor surgical judgment. The literature contains many such cases treated conservatively too long with a subsequent loss of the kidney or even life. Surgical intervention, if performed early, may preserve a severely damaged kidney, yet the degree of shock must first be determined and treatment instituted for its control before surgery is begun. The most conservative treatment for these patients is prompt exposure of the kidney, repair when possible or early nephrectomy. When doubt persists concerning the extent of the renal injury after all diagnostic procedures have been done, an early exploratory operation is preferable to prolonged expectant treatment.

DR. GEORGE F. CAHILL, New York: Dr. Sargent's paper is timely. Too often diagnostic methods are used by those not familiar with them. In tumor of the kidney an intravenous urogram may not establish a diagnosis but may need retrograde pyelography. So too in renal injury. Renal injuries vary. They may be only a minor portion of a profound injury. With penetrating wounds of the abdomen the kidney is often not a major part of the picture but is obscured by intestinal or other injuries and in the late war the infrequency of renal injuries was due to the fact that most of those seriously wounded died on the field. When the kidney is the major trauma there may be many sources. Automobile accidents are frequent causes especially to those occupying the rumble seat. The symptom most frequently seen is hematuria. When it occurs it should be investigated. I do not see any objection to the use of an intravenous urogram in such cases. If the patient is in shock naturally that condition should be relieved by transfusion and other therapeutic aid and then the intravenous urogram done. The secretion from the uninjured kidney shows that it is present. The injured kidney may or may not secrete. If it does and well, then the injury most likely is not severe and expectant treatment is in order. If the kidney does not secrete and an increasing hematoma is present in the flank, then, operation being contemplated, a retrograde pyelogram may be done. If marked local hemorrhage is present, repair of the kidney must be early if the kidney is to be saved. Infection occurring in a

Fig. 5.—In this gunshot injury retrograde pyelography proved of uncanny accuracy in predicting that, except for an intact upper pole, the kidney would be found shattered beyond recognition.

confusion, however, there was one feature of her case that was perfectly clear from the very start. Thanks to our pyelogram, we were never in the slightest doubt about the condition of her injured kidney and what had to be done about it.

CONCLUSION

In closing this scanning recital of certain observations concerning kidney injury permitted through many years of an active emergency service, I should like to stress from among them:

1. Immediate examination of urine, either voided or catheterized, must be made absolutely routine in all accident cases. Considering the danger that lurks in hemorrhage and particularly the terrible consequences of urinary extravasation when it occurs, altogether too much is at stake to neglect this simple and easy precaution.

2. Gross hematuria in accident cases demands absolutely accurate diagnosis. Many times it proves to be of no particular consequence, but many times also it bespeaks an injury of first magnitude.

3. Intravenous urography can be quite useful as a scout procedure in those accident cases in which the urinary tract is suspected. It must be followed by more exact studies, however, unless sharp outline per-

traumatized kidney usually ends in destruction of the kidney. Retrograde pyelography may increase the incident of infection but if one cannot succeed in establishing the renal damage by intravenous urography one then must use other means for its estimation.

DR. W. CALHOUN STIRLING, Washington, D. C.: My experience has been that in the majority of the cases of injuries of the kidney the diagnosis can be made by intravenous pyelography. A recent review of thirty-four cases gave a positive diagnosis in twenty-three, and in only seven instances was it necessary to do a retrograde pyelogram. I believe that instrumental pyelography should be reserved solely for cases in which bleeding continues with unsatisfactory pyelograms. In the presence of severe contusions the first intravenous pyelogram may be unsatisfactory, whereas if it is repeated in from twenty-four to forty-eight hours it will frequently show a good shadow. A majority of the cases reported as ruptures of the kidney are only contusions and respond to conservative measures. My experimental work and clinical studies indicate that, in the presence of severe injury to the kidney, operative intervention is more likely to give a good result than is the conservative method. The literature shows an increasing number of cases with permanent partial loss of function in which the kidney was allowed to heal spontaneously. I have found that when early surgical intervention is instituted, that is the capsule incised, clots evacuated, gauze packs inserted or fat pads sutured over the lacerated area, functional restoration of the kidney will in most instances result. Goldblatt and his associates have shown that hypertension may be produced experimentally by partially clamping the renal artery. Weiss and Parker estimate that pyelonephritis is responsible for at least 20 per cent of the cases of malignant hypertension due to vascular changes. Severe injuries of the kidney produce marked vascular damage which may later cause ischemia of the kidney, followed by hypertension. Patients with renal injuries should be watched for evidence of hypertension. The loss of blood in renal injuries makes anemia an important factor to consider during the convalescence. This complication was not due to the simple loss of blood but to the liberation by the injured kidney of some substance capable of causing toxic destruction of red blood cells. Possibly the degeneration of kidney tissue releases some toxic substance capable of affecting adversely the red blood count and probably the blood pressure. Fat was found to be much superior to muscle in arresting hemorrhage. It is my opinion, based on an experimental as well as a clinical study of a series of cases, that if the kidney is severely injured one should always explore and institute conservative surgical packing, suture and drainage.

DR. VINCENT J. O'CONOR, Chicago: Apropos of Dr. Sargent's paper, practically all of which I agree with, I wish to point out one inference which he makes with which I thoroughly disagree and which I think, since these proceedings are a matter of widespread printing in *THE JOURNAL*, should be clarified. That is with regard to the length of rest in the cases treated palliatively. Dr. Sargent said in certain instances that individuals could be back at work in a few days following a rather massive hemorrhage which cleared up quickly. In three instances in my own experience in which a more or less minor kidney injury, at least from a clinical point of view at the time of the injury, apparently responded successfully to palliative treatment the individuals, against orders, went back to an active life and all three of them returned with massive hemorrhage which necessitated surgery, coming on as long as four weeks after their discharge from the hospital. One of these patients, who had a massive hemorrhage which lasted only twenty-four hours, responded quickly to four or five days of rest in bed, left the hospital against orders on the tenth day, and returned three and one-half weeks later with a kidney which was completely broken in two following the lifting of a heavy suitcase. Two boys with football injuries were allowed to return to active life. Both resumed playing football within three weeks and both returned with massive hemorrhage which necessitated surgery. I believe that these patients who are treated palliatively should be kept at rest, certainly a period of two weeks, and that their physical activity should be limited for from four to eight weeks at a minimum.

DR. JAMES C. SARGENT, Milwaukee: In making a point of the fact that many renal injuries prove to be quite minor and soon healed, perhaps I gave the impression that I underrated the importance of prolonged bed rest when real injury has occurred. However, I wish it clear that I agree with Dr. O'Connor in the wisdom of keeping these patients down on their backs for a considerable time.

GEOGRAPHIC VIRULENCE OF MASTOIDITIS

MERCER G. LYNCH, M.D.

NEW ORLEANS

For some time the question of geographic variation in the incidence of mastoiditis has been of interest and an attempt at an explanation has thus been undertaken. There is much literature regarding climate in general terms. The weather and season function together as the most important environmental factor from the time of birth to the time of death of an individual. Acute infections of the mastoid reach their peak in the spring following the cold weather, not in the summer, and do not again begin to rise until the fall, when changes, often sudden, are seen.

Throughout the United States there is every variety of climate and of weather conditions. Too, one sees a great variety of peoples from every nation scattered throughout the country. These people and their respective living conditions as well as their racial immunity make them susceptible or resistant to different disease conditions.

An organism virulent to one group of individuals may have little or no effect on another group, and the reverse may be the case. Different diseases are also more prevalent in some localities than in others. However, *Streptococcus haemolyticus* is universally found throughout the country. Of nasal cultures taken at random throughout the country, 50 per cent of them from any area showed streptococci and the rest were made up of other organisms, so that truly the streptococcus is found in every locality, as it is the most common organism cultured at the time of operation on the mastoid.

Why is it that along the Gulf Coast from Texas through Florida there are relatively few cases of mastoiditis in proportion to the population? As we progress northward along the Eastern Seaboard the incidence and number of cases steadily increase until in Massachusetts and Maine the peak is reached. The same procedure is true for the Mississippi Valley and the country west of the Mississippi. What part does climate play, especially in those localities in which the climate is so variable, and what part do diet, the habits of the population in regard to these different localities and climates, the foods and the incidence and degree of illness of the population play? All these questions fill a rather large order, but an approach has been made to arrive at some conclusion as to just why this should be.

We who live in the deep South in proportion to our population see a rather small percentage of mastoiditis. As one journeys northward, the incidence increases in proportion to the population until the peaks are reached in the northern limits of the United States.

Through the cooperation and assistance of men in other cities throughout the United States, cultures of hemolytic streptococci have been received and indi-

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

vidual studies made under different conditions of climate, diet, exercise and illness, the guinea pig being used as the host.¹ When the cultures were received all were transplanted to blood agar and then standard solutions were made so that all solutions were of equal strength for experimental and testing purposes. These solutions were all subjected to various temperatures of heat and cold such as are found throughout the country and to sudden changes in temperatures such as are found in certain localities. Those organisms obtained from the areas having such changes were more resistant than those taken from more uniform climates, where many were inhibited or killed. Therefore the organisms themselves lose some of their virulence and living powers when accustomed to a more uniform climate. But those that remained became in time as virulent as the organisms accustomed to such changes.

Animals of the same age were injected intraperitoneally with the original solutions. Those cultures received from the Middle West and Northeast sections of the country when thus injected produced early peritonitis and death as compared to a longer illness in those from the Central and Southern states.

Animals were then placed under conditions simulating their respective climates for a period of time and the organisms reinjected. The death rate was increased as well as the degree of illness, and the duration was shortened for those animals receiving solutions from the North and the East, the degree of illness increasing as well as the duration of the illness lengthening as one approached the southern climate. These animals, killed and examined post mortem at various stages of their illness, showed interesting conditions. Those injected with the first group showed an early tendency to spread, with little walling off of the infection. The animals that survived the first period of illness showed a late tendency to walling off of the infection. These corresponded with the conditions found at autopsy of animals that succumbed, showing generalized peritonitis with localizing areas or pockets which were walled off.

The animals injected with the second group showed a tendency to an earlier walling off. Many of these survived and showed a completely walled off abscess. However, the tendency was to an early walling off, then slow breaking down of the abscess and a final generalized peritonitis. To draw conclusions, it would seem that early operation is indicated in the first group, whereas one may be inclined to follow the progress of the disease in the second group, but generally it is advisable to operate in both cases, the main factor being time.

Animals were placed under conditions of warmth and sunlight and fed high caloric and high vitamin diets. They were then injected with the most virulent strains from the North and the East. Likewise animals were again placed in cold climates with little sunlight and limited space for exercise, and these were injected with the strains from the South. Of the first group the virulence was markedly reduced, although they still showed a tendency to an early death rate as compared to the same group given the injection from the Middle and Southern states. Those receiving injections of the lesser strains but under the colder habitat showed a lowered resistance and an increase to early develop-

ment of infection. From this it is concluded that those areas of the country where the climate varies markedly, where extremes of cold are encountered and where open air exercise is thus limited, over a period of time the resistance is lowered and the population is thus more susceptible to infection—this, coupled with the fact that the infection gains virulence because there is less in the natural elements to combat and decrease the virulence. By these factors are meant fresh air, sunlight and exercise.

Clinically, these facts are substantiated by reports showing that the highest incidence of mastoiditis is in March. This peak is reached after a gradual rise beginning in December and January, or at the onset of the extremes of cold. After March there is a steady decline, until the low point is reached in August, the time of maximum sunshine and, although hot, a more regulated and even temperature.

Of the 100 cases of mastoiditis studied by Tomb, the majority were in children, but it is noteworthy that twenty of these patients were housewives who had nursed children with infections of the upper respiratory tract. They had contracted the infection and developed otitis media and mastoiditis. These cases occurred in the winter months when there were poor ventilation of rooms and little or no time for sunshine or fresh air. These conditions are also seen among interns and residents coming from warm climates to be established in hospitals in the East or West and likewise those from the East going South. The majority of these men have a longer period of sickness against their records and are more prone to complications than are the interns who remain in the locality or area to which they are acclimated.

A great deal of work has been done with vitamins in connection with the prevention of disease, the building up of resistance and the elimination and healing properties of tissues in which these vitamins have been used. Space does not permit of a detailed report, but certainly work in this regard shows that, along with the elements of climate, exercise and fresh air, diets rich in vitamins make for better resistance of the patient and a greater facility to throw off infection than by those fed only ordinary diets with no regard to vitamins. Climates vary throughout the country and so do organisms. Individuals likewise vary and are more susceptible or resistant. Generally in milder climates the organisms are themselves less virulent and, because of open air ventilation, sunshine and more access to natural vitamins, the resistance is increased. All these factors must be taken into consideration in an explanation of the geographic virulence and incidence of mastoiditis.

921 Canal Street.

ABSTRACT OF DISCUSSION

DR. NOAH D. FABRICANT, Chicago: It is possible for any number of environmental factors, such as emotion, diet, infection, intoxication and fatigue, to influence a person, but it is extremely difficult to evaluate them. The weather, however, can be measured. Thus, daily temperature changes are measurable, as are likewise barometric pressure, daily average wind velocity, sunshine and daily precipitation. Every physiologic adjustment necessitated by weather alteration is apt to find reflection in any region of the body that is inadequate. This will find expression either in unusual symptomatology, in change in function or in actual pathologic change in the various organs of the body—factors that are measurable. Consequently we are able to measure both the stimulus, i. e. the weather, and the effect on the human being, i. e. the clinical, biochemical and vasomotor changes that are induced in man. We must adjust ourselves

1. The following men cooperated in sending cultures and only by this means was the work completed: Drs. Fred Pollock, Chicago; Paul Mertins, Montgomery, Ala.; Lester Brown, Atlanta, Ga.; Merrill Wattle, Jacksonville, Fla.; Fred Ogden, Boston; Wallace Dean, St. Louis; Harold Smith, Pomona, Calif.; John Shea, Memphis, Tenn., and Fred Harned, Hopkinsville, Ky.

periodically to two wholly different types of atmosphere or air masses. We speak of these as polar air masses (cold fronts) or tropical air masses (warm fronts). Chilling of the body surfaces causes constriction of the blood vessels of the skin and this is followed by a constriction of the blood vessels of the nasal mucous membrane. A prolonged ischemia of the nasal mucosa reduces the local resistance and favors infection. Local chilling of the body surfaces is often induced by inclement weather. In the wake of a cold front there is a change in the functional status of the mucous membranes of the nose and throat. From a few hours to one or more days may elapse before the clinical symptoms make their presence felt. Although one cold front may be passed without instituting harm, it is often the repeated or superimposed cold front that results in further damage. In a study of the onset of acute otitis media and mastoiditis, I have found that the precipitation of these diseases occurred most often when there was a fall in the atmospheric temperature. The vasomotor and biochemical changes induced in the human being by the passage of a cold front are accompanied by vascular spasm, increased blood pressure and a relative increase in pH . Gradually the vascular spasm is dissipated, the blood pressure falls and the tissues become relatively more acid and hydrated. At such a time the individual is apt to experience the feeling of fatigue, and during this period bacterial penetration is more apt to occur. Changing environment produces changing energy demands on human organisms that are no longer adequate. Under the continuous pendulation of temperature, humidity and barometric pressure the population constantly swings from a phase in which the vascular spasm is enhanced to one in which vascular dilatation is augmented, and vice versa.

DR. LESTER A. BROWN, Atlanta, Ga.: I have gathered information from each individual record of mastoiditis of three Atlanta hospitals covering a period of six years, 1934-1939 inclusive, using this span of time because of the discussion that follows the present use of sulfanilamide and its derivatives on the incidence of mastoiditis. This comprises an estimated one half total Atlanta survey. It is divided into the three years before the introduction of sulfanilamide and the three years after. In the first group the total number was 197, in the second 200. Of the first group 43.1 per cent were male, in the second 50.5 per cent; 46 per cent were right in the first group as compared with 56 per cent in the second; 13.7 per cent were chronic in the first group and 25 per cent in the second. In the group preceding sulfanilamide 5.56 per cent had complications, while in the group after the use of sulfanilamide complications appeared in 8 per cent. The mortality in the first group was 3.04 per cent and in the second 3 per cent, about the same. The mortality was found to be caused by meningitis in seven cases, pneumonia in one case, following spinal puncture in one case, septicemia one, petrositis and meningitis one and myelogenous leukemia one. Having found these statistics for Atlanta, I then converted them into death rates per hundred thousand of population for comparison with the United States Bureau of Vital Statistics, which figures are for the United States as a whole. They are 1.3, 1.2, 1.3, 1.6, 1.3 for the first group, which puts the assumed Southeast in a class of about average mortality, but in the first two years of the second group Atlanta's mortality was about twice as high as the average for the country as a whole. In 1939, however, for which I do not have a bureau figure, the mortality has dropped to less than one half. From these statistics it would seem that the geographic virulence of mastoiditis as regards the Southeast is slightly higher than an average for the United States as a whole.

DR. MERCER G. LYNCH, New Orleans: Throughout the country the anatomy of the mastoid doesn't vary. The methods of treatment of acutely and chronically inflamed ears do not vary to any great extent. Therefore, another problem enters into the question as to why there should be so much more mastoiditis in one part of the country as compared to another with regard to population, and because of this an attempt has been made to study the virulence of the organism with the idea in mind that, all factors being equal, it was the virulence of the organism that contributed to a great extent to the increase of mastoiditis throughout the country.

REHABILITATION FOLLOWING ACUTE CORONARY ARTERY OCCLUSION

ARTHUR M. MASTER, M.D.

AND

SIMON DACK, M.D.

NEW YORK

It is only during the past decade or two that the clinical recognition of coronary occlusion has become well established among general practitioners. There has therefore been a limited period for follow-up study of patients recovering from the acute attack, and of necessity relatively little accurate information is available concerning the future course of the disease. This is true particularly concerning the degree of economic restitution following an attack.

Since coronary occlusion is very common,¹ occurring in all strata of society, it is of importance from a therapeutic and prognostic standpoint for a physician to know whether the patient may return to work. Many questions concerning the effect of work following coronary occlusion have remained unanswered. For example, does work increase the susceptibility to further attacks of occlusion, to death, to heart failure, to angina pectoris? If angina pectoris is present, should the patient be permitted to work? Does the presence of a slight degree of heart failure preclude the possibility of working? There is wide variation of opinion concerning the answers to these questions. Formerly it was commonly believed that coronary occlusion always entailed complete and permanent disability, and even now millions of dollars are paid annually by insurance companies to men who have suffered a coronary occlusion, regardless of their present physical condition. However, a number of authors² including ourselves³ have recently pointed out not only that the immediate prognosis of coronary occlusion is steadily improving but that the patient may recover completely and remain in good health for many years. Furthermore, one of us showed that many patients recovering from the acute attack returned to work. The first complete report⁴ on this subject, comprising seventy-five cases followed in private practice, showed that at least 62 per cent of the patients returned to their usual routine of life or work and that 14 per cent resumed light to moderate activity. Only 8 per cent of the patients were completely disabled. Other authors⁵ have subscribed to our point of view.

This follow-up study consists of a much larger series of cases. It concerns itself not only with the problem of how many return to work but also with factors which favor economic restitution.

MATERIAL

The series consists of 415 patients, 185 private and 230 hospital ward, who had sustained an acute coronary occlusion and had survived the acute attack⁶ (table 1). Detailed information concerning these patients' activities following the attack was obtained by the questionnaire reproduced here. Many of the private patients were also seen frequently at the office and practically all the ward patients were observed in a special follow-up clinic.

WORK QUESTIONNAIRE

Name: Age: Date of Attack:

1. What kind of work, if any, did you do before your illness?
2. Have you done any work since your illness?
3. If you have not worked is it because:
 - (a) you were advised not to (if so, by whom)?
 - (b) you are receiving sickness or disability insurance?
 - (c) you have been unable to find a job?
 - (d) you are unable to work?
 If you are unable to work, what is the reason?
4. If you have worked:
 - (a) How soon after you left the hospital did you return to work?
 - (b) What kind of work have you been doing?
 - (c) Are you able to work full time? Part time?
 - (d) If you are not able to work full time, what is the reason?
 - (e) Do you find it difficult to work? If so, why?
5. Have you any disability insurance from which you could receive benefits if you could not work?

There were 342 males and seventy-three females. Seventy-five per cent of the patients had suffered one attack, 22 per cent a second attack and the remainder a third or fourth attack when they first came under our observation. Two fifths of the patients were in the sixth

All types of occupation and all strata of society were represented (table 6). It will be noted that more than 50 per cent of the ward patients were manual workers or laborers, while these occupations composed only 11 per cent of the private group.

decade of life and the majority of the remainder were in the fifth and seventh decades.

The longest period of observation was fifteen years and the average about three years (table 2). Eighty patients were followed five years or more.

6. Of 857 patients with acute coronary occlusion observed during the past ten years, 662 survived the acute attack. Of these, 247 were lost from observation or had sustained their attack too recently to be available for study, leaving a total of 415 cases, which form the basis for this report.

The following points were considered: the percentage of patients returning to work; whether the patient experienced any symptoms of impaired cardiac reserve during work; the influence of age, sex, number of attacks sustained and occupation on the incidence of return to work; the time of return to work; the reasons for not resuming work; the incidence of further attacks of occlusion, and the mortality rates of those who returned to work as compared with those who did not.

RESULTS

Fifty-three per cent of all patients returned to work following recovery from the attack; these included 57 per cent of private patients and 50 per cent of ward patients. In 32 per cent the work was full time and in 21 per cent part time (table 3). In general, the private patients fared better than the ward, the degree of economic restitution being greater in the former group (table 4). Thus 42 per cent of private patients resumed full time work, whereas only 23 per cent of the ward patients did so.

The factor of greatest importance in determining return to work was the age of the patient (table 3). The younger the patient the more probable is his return to work. Thus 75 per cent of those in the fourth decade and only 43 per cent of those in the seventh resumed their occupation. This is not surprising, since even in the general population the incidence of those in gainful employment probably decreases with age.

Sex was no factor in influencing return to work (table 4), for almost as many women (51 per cent) resumed their former activities as did men (54 per cent).

The second most important factor was the number of attacks of occlusion sustained by the patient (table 5). It is well known² that the immediate prognosis, including the mortality rate, of an initial attack is better than

that of a second or third attack. Similarly the percentage of patients returning to work after a first attack exceeded by far that of patients who had sustained a second or third attack, the percentages being 59, 38 and 23 respectively. It is noteworthy that one man resumed his occupation after a fourth attack.

TABLE 5.—*Influence of Successive Attacks*

		Full	Part	Total
1.....	312	113	71	184 (59%)
2.....	90	17	17	34 (38%)
3 and 4.....	13	2	1	3 (23%)
Total.....	415	132	89	221 (53%)

Previous occupation played some role in determining return to work (table 6). Thus 84 per cent of professional persons, particularly physicians, and 67 per cent of white collar and office workers resumed their occupation, whereas only from 50 to 55 per cent of the remaining groups did so. Only occasionally did a patient take up a more sedentary occupation but not infrequently he did only light work. This was true chiefly among manual workers and laborers; more than half of those who resumed work did so on only part time, whereas almost all the professional persons and office workers worked full time. However, this discrepancy may be explained in part by the fact that the professional and executive classes are able to lighten their activities although they seem full time and are so described.

It will be seen in table 6 that twenty patients had no occupation or were retired prior to the attack. Although we have included all these patients in the group that did not return to work, it should be noted that only a few were invalids or bedridden. The majority were able to carry on the ordinary activities of daily life.

In table 7 we have tabulated the time of return to work following discharge from the hospital or after getting out of bed (usually a four to eight week period).

Of the 169 patients for whom this could be determined, 92 per cent resumed work within one year, 76.5 per cent within six months and 54 per cent within three months of discharge. Ten patients continued working through the entire attack, the diagnosis of coronary occlusion being made later on the basis of history and changes in the electrocardiogram.

Although the majority of patients resumed work, almost half of these experienced some degree of pain, dyspnea or weakness during work (table 8). Ward patients predominated among these, particularly housewives, laborers and white collar workers. However, the symptoms were not severe enough to keep them from their ordinary activities. It should be remembered that in 50 per cent or more of these cases similar symptoms were probably present prior to the attack of coronary occlusion.

Inability or failure to return to work (table 9) was usually due to physical disability, the particular complaints being angina pectoris, weakness or dyspnea. Heart failure was also common. A large group of patients did not work because they were advised against it by their physicians. It seemed to us that a large percentage of this group could have worked if it had been necessary. Many patients held disability insur-

ance, particularly in the private group. Twenty-eight of the latter and two ward patients gave this as the sole reason for not returning to work. Not a few patients felt well enough to resume their occupations despite the disability insurance they held. Several patients did not work because it was no longer necessary for them to do so or because of inability to find a job.

An attempt was made to determine the influence of return to work following coronary occlusion in predisposition to a further attack or to congestive failure by comparing the incidence of these in the group that worked and in the one that did not (table 10). One difficulty in doing this is the fact that the nonworkers included a large number of very sick patients. Nevertheless it is evident that the number of subsequent attacks was no greater in the working group than in the nonworking group. This is true also of the number of patients who developed congestive heart failure or who died subsequent to the acute attack. It appears, therefore, that return to work following recovery from the attack did not adversely influence the occurrence of further attacks of coronary occlusion or of heart failure.

COMMENT

Not only has there been improvement in the immediate prognosis of the acute attack of coronary occlusion² but our present observations indicate also quite definitely that the outlook for the future is hopeful for the patient who survives the attack. We have found

that approximately half the number of patients are able to resume their former occupations within one year, and usually in less than six months. To be sure, many of those who return to work complain of angina, dyspnea or weakness, but these symptoms are usually mild and frequently no more severe than they were prior to the attack.

We have observed many of these patients at regular intervals and have gained the distinct impression that, as a rule, their symptoms were not directly connected with the fact that they were employed but would have been present in any case. Only occasionally has it been our experience that symptoms would develop while a patient was employed which would disappear when he gave up his job. Usually the symptoms persisted. It would seem that, following coronary occlusion, patients may be placed in two general groups. One includes those who recover quite well and can resume their usual mode of life although they may have some complaints. The great majority of this group are patients below the age of 50 who have sustained only one attack of coronary occlusion. In the other group are those who never completely recover from the occlusion but are left with a persistent anginal syndrome or evidence of heart failure. The latter patients are unable to return to work whereas the former are not only able to do so but are usually

* Angina pectoris, dyspnea, weakness.

unaffected by the effort, even though it is frequently no less arduous than that sustained prior to the attack.

It is our opinion also that return to work is not a factor in the occurrence of further attacks of coronary occlusion. We have already presented evidence⁷ in 1,500 attacks of coronary occlusion that the onset is not related to any external factor or to any particular occupation or social class. Coronary occlusion is the end result of a progressive atherosclerotic process and occurs as often in the sedentary individual as in one engaged in active work. In the present series the incidence of further attacks of coronary occlusion or heart failure in those who return to work was not unduly large and was not greater than in those who remained invalids or led a sedentary life. Similarly the number of deaths was not higher.

It is obvious from our observations that sustaining an occlusion of a coronary artery is in itself no reason for permanent disability. Indeed, frequently the temporary disability does not extend beyond from three to six months, and the patient can return to his previous occupation. If the work is strenuous, such as manual labor or factory work, a thorough examination before return to it and periodically thereafter is essential in order to be certain that the condition of the heart

is satisfactory. In such an occupation one faces the problem of compensability if another occlusion occurs or heart failure sets in, but we have already indicated our belief that these occur irrespective of occupation.

The indications of disability following coronary occlusion are similar to those in any case of coronary

artery disease. These are chiefly the presence of heart failure or a severe anginal syndrome, particularly at rest or during habitual activity. Occasionally extreme weakness may be persistent as the only symptom of disability. A history of recurrent occlusion, especially in association with aneurysm of the heart, is a legitimate reason for disability, although even such patients sometimes carry on comfortably. The same is true of patients whose blood pressure is very much elevated. Even in the presence of these indications of disability it may yet be advantageous to permit some degree of activity, since it may be tolerated without adverse effect and may benefit the patient psychologically. Invalidism has too long been emphasized in heart disease, and a hopeful outlook on the part of the physician may guide the patient into a useful and enjoyable life.

SUMMARY AND CONCLUSIONS

A follow-up study after coronary occlusion was made to determine the incidence and degree of economic restitution and the various factors influencing the latter.

Four hundred and fifteen patients were followed for from six months to fifteen years after the attack. There were 185 private and 230 ward patients of all ages, occupations and walks of life.

More than half the patients returned to work on full or part time. Half of this group resumed work within three months of discharge, three fourths within six months and nine tenths within one year.

The percentage of patients returning to work was higher in the younger age groups, particularly those

under 40, and in those recovering from an initial attack. The percentage was about the same in males and females.

The professional and white collar classes resumed their work more frequently than did persons engaged in other occupations.

The chief cause of failure to return to work was physical disability resulting from angina pectoris, dyspnea or weakness. Other reasons were advice not to work and disability insurance.

7. Master, A. M.; Dack, Simon, and Jaffe, H. L.: The Relation of Various Factors to the Onset of Coronary Artery Thrombosis, *J. Mount Sinai Hosp.* 3: 224 (Jan.-Feb.) 1937; Factors and Events Associated with the Onset of Coronary Artery Thrombosis, *J. A. M. A.* 109: 546 (Aug. 21) 1937; The Precipitating Factors of Coronary Artery Occlusion, *Indust. Med.* 8: 327 (Aug.) 1939; Activities Associated with the Onset of Acute Coronary Artery Occlusion, *Am. Heart J.* 18: 434 (Oct.) 1939.

About half the patients who returned to work complained of pain, dyspnea or weakness which were not of sufficient degree to cause disability. It is our impression that the work did not aggravate these symptoms or predispose the patient to them or to further attacks of coronary occlusion or heart failure.

An attack of acute coronary occlusion in itself is not sufficient reason for permanent disability. Complete recovery and full or partial economic restitution are common. Heart failure or a severe anginal syndrome is evidence of complete disability.

ABSTRACT OF DISCUSSION

DR. HARRY E. UNGERLEIDER, New York: Our increased knowledge of heart disease in recent years has brought a more encouraging outlook. It is a far cry from individual case reports of recovery from coronary occlusion which were cited in the literature a decade ago to the hopeful prognosis for the majority revealed by the authors' study. While a relatively optimistic view toward coronary occlusion now prevails among cardiologists there continues to be an unwarranted dread of this disease. The feeling is widespread among the laity and also with the medical profession that an individual who has sustained an attack of coronary thrombosis is "through" and is doomed to spend his remaining days in complete invalidism. Studies such as the present one should dispel this erroneous concept, which has caused needless fear and unhappiness to thousands of individuals with this common disease. Apart from this problem as it applies to the management of individual cases there are two important aspects, the relation of coronary disease to industry as regards industrial law and the subject of disability insurance. There is a deplorable lack of uniformity in different states in the legal attitude toward the responsibility of industry to employees with heart disease regarding both employability and compensation. There is a reluctance on the part of industry to accept for employment individuals known to have heart disease because of possible liability for subsequent illness. In fairness to both parties, it would be advisable to have subjects with heart disease sign waivers removing liability for further complications. It is hoped that this important subject, which has been largely neglected by the medical profession, will receive the consideration it richly deserves and will result in some uniformity of procedure which is now woefully lacking. The subject of disability insurance is of great practical importance. Coronary thrombosis is no longer regarded in itself as cause for total and permanent disability unless there is some residual impairment of cardiac function such as angina or evidence of heart failure. Insurance companies for years have carried out a rehabilitation program in cases of coronary thrombosis. Following a temporary period of total disability after the attack a cooperative attempt is made to restore the subject to his previous occupation or another less strenuous, and disability payments are continued until it is definitely ascertained whether work can be continued. This program has proved most satisfactory to both the insured party and the company, and in a large number of cases the psychologic effects of invalidism, often worse than the disease itself, have been successfully averted. It should be a primary objective in the treatment of coronary thrombosis to make definite efforts to avoid invalidisms instead of instilling needless fear and restrictions, as has been our practice too often in the past.

DR. CARY EGGLESTON, New York: I think we have been too long afraid to permit our patients, after a coronary occlusion, to attempt rehabilitation. We have been misled partly by our own fear but chiefly by the patient's fear, which has been instilled in many by physicians who have had too little experience with the ultimate outcome in these cases. We ought to about face in our treatment of these patients and make it the primary goal to tide them through the attack with an eye to their rehabilitation. A great deal of the disability residual in some of these patients who do not work is purely a psychic disability. Where conditions in such patients alter from circumstances without, over which they have no control, a number of

these patients who previously were unable or believed themselves unable to work have successfully resumed occupation on a satisfactory or economic level. We must lay greater emphasis on rehabilitation. As a profession we owe a duty to ourselves to educate our brothers in the recoverability from coronary occlusion.

DR. CLIFFORD KUH, New Haven, Conn.: Yesterday at the General Scientific Meeting in discussing the management of patients with heart failure Dr. Samuel A. Levine mentioned that sometimes we are a little fearful in treating them. In one case of coronary thrombosis when other measures failed he got the man well by getting him out of bed and into a chair. I think the point is a significant one to bring out here, namely that we might be fearful not only in our after-care but in our therapeutics. In this case the man had congestive failure with hydrothorax. By getting him in a chair the edema was thrown to the extremities. This relieved respiration and the man did very well.

OCCIDENTAL BERIBERI WITH CARDIOVASCULAR MANIFESTATIONS

ITS RELATION TO THIAMIN DEFICIENCY

SOMA WEISS, M.D.

BOSTON

In 1936 we¹ described the existence of "wet" beriberi with cardiovascular disturbances as a nutritional disease of regular occurrence in Boston and its vicinity. We presented evidence indicating that this disease is related to vitamin B deficiency and that administration of thiamin chloride or vitamin B concentrate benefits patients with this condition. Since this first report, further studies have been conducted on the clinical, physiologic and chemical characteristics of beriberi and on its treatment.² We have induced cardiac disturbances in animals fed on a thiamin-deficient diet and demonstrated that their cardiac disturbances disappeared promptly following the administration of thiamin chloride.³ We have investigated the metabolism of the myocardium in vitamin B₁ deficiency⁴ and made a systematic search to evaluate the role of certain intermediary metabolic products, such as lactic acid, pyruvic acid, methyl glyoxal, glyceraldehyde and adenylic acid, in the induction of cardiac disturbances.⁵ In the light of these and more recent observations, as well as of reports of other investigators, it may be of interest to summarize the present status of our knowledge of "Occidental beriberi" with cardiovascular manifestations.

Read in part before the Eighth American Scientific Congress, Washington, D. C., May 13, 1940.

From the Medical Clinic of the Peter Bent Brigham Hospital, the Boston City Hospital and the Department of Medicine, Harvard Medical School.

Since this article was written, the term "thiamine hydrochloride" has been adopted as the Pharmacopoeial name for the substance referred to here as thiamin chloride.

EVIDENCE FOR THE EXISTENCE OF BERIBERI
IN THE UNITED STATES

In the Orient, beriberi is at times a disease of common occurrence and of serious consequence. It may appear as (1) neuritic or "dry" beriberi with symptoms and signs related to the nervous system; (2) the edematous or "wet" type in which the clinical picture consists mainly of diffuse dependent and nondependent edema, quite similar in distribution to that seen in glomerulonephritis, toxemia of pregnancy and nephrosis, with the serous cavities, including the pericardium, often containing varying amounts of fluid; (3) the cardiac type, which in its pronounced form may be associated with high venous pressure and dilatation of the heart. The clinical reports from the Orient emphasize the fact that "mixed types," i. e. combinations of the various manifestations of beriberi, are common.

It is essential to appreciate the fact that in many of the older clinical reports of cases of beriberi the cardiac size was determined only with the aid of percussion and hence is unreliable. Aalsmeer and Wenckebach,⁶ on the basis of their studies of beriberi in Java, state that dilatation and failure of the right ventricle characterize this type of heart disease and that the circulatory failure is "right sided failure." Wenckebach⁷ postulated that the blood flow is relatively rapid in beriberi with heart disease and observed that the symptoms and signs of circulatory failure in beriberi become accentuated after the administration of epinephrine and improved after pitressin. On postmortem examination he observed edema and "hydropic" degeneration of the myocardium.

In the United States, chiefly in the publications of Shattuck,⁸ Wechsler⁹ and Minot, Strauss and Cobb,¹⁰ it has been suggested that in the etiology of certain types of polyneuritis, including alcoholic polyneuritis, nutritional deficiency and lack of vitamin B₁ play a role. Our establishment subsequently of the occurrence of "wet" beriberi in the same nutritional disorders added evidence to support the claim that these polyneuritides are of the same etiology as the polyneuritis of "dry" beriberi in the Orient.

In our earlier studies we compared the clinical, physiologic and morphologic characteristics of the disease with those observed in the Orient. Both the clinical studies¹¹ and subsequent experiences revealed that the same types of beriberi described in the Orient exist in this country. Thus we have reported cases presenting severe polyneuritis and electrocardiographic changes, tachycardia and a normal size heart; polyneuritis and severe congestive failure of the heart associated with electrocardiographic changes but with a normal size heart; and a severe degree of dilatation of the heart with little or no electrocardiographic changes, associated with a moderate or severe degree of edema. We found that the type of circulatory failure in "wet" beriberi might be either right or left sided or both. In addition to the clinical picture of right ventricular failure described by Aalsmeer and Wenckebach, orthopnea, cardiac asthma, x-ray and clinical signs of pulmonary

congestion and edema were also observed. The onset of symptoms might be either gradual or quite sudden. Breathlessness, palpitation and tachycardia, gallop rhythm, murmurs and venous congestion, prone to become accentuated on exertion, were present even at rest in the advanced cases, and in these severe cases bounding pulsation of the arteries with "pistol sounds" developed. In some patients bed rest alone resulted in improvement, but in others unexpected accentuation of the circulatory failure and collapse developed at rest, resulting in unexpected death. A strong tendency to circulatory collapse and shock was noted particularly in the presence of respiratory infections. The relative prominence of cardiac or peripheral vascular dysfunction varied considerably. Severe polyneuritis was usually associated only with a mild degree of congestive failure of the circulation, because the presence of such polyneuritis interfered with locomotion and work and hence protected the heart.

The presence of edema, varying in degree from slight to severe, was independent of, though at times influenced by, the protein content of the blood. The edema, while dependent in some instances, was usually diffuse and interstitial. Thus loss of from 40 to 50 pounds (18 to 23 Kg.) of fluid occurred in persons who at first appeared robust and at the time of admission only slightly edematous. As in glomerulonephritis or in toxemia of pregnancy, the protein content of the edema fluid was unusually low. During the edematous stage, oliguria with highly concentrated urine, and at times slightly elevated nonprotein nitrogen of the blood, was present and administration of fluid had little effect on the concentration of urine. Following treatment a continuous maximal diuresis with low specific gravity developed.

The importance of thiamin deficiency in organic heart disease cannot be determined at present, mainly because of the lack of a reliable chemical method for measuring minute amounts of thiamin. As anorexia and unbalanced diet frequently exist in cases of organic heart disease, thiamin deficiency may well accentuate heart failure. We have encountered such cases.¹²

Physiologic studies have indicated that in patients with "wet" beriberi, particularly those with high venous pressures and edema, the arterioles are dilated, the utilization of oxygen in the venous blood is small and the velocity of blood flow is absolutely or relatively rapid. The vital capacity of the lungs is often severely reduced. In some instances, administration of epinephrine temporarily aggravated the condition, while pitressin exerted temporary improvement. In several respects the character of the heart and circulation in "wet" beriberi is similar to that in arteriovenous aneurysm and thyrotoxicosis.

The electrocardiograms often revealed changes, the most common finding being depression and inversion in the T waves and prolongation of the electric systole. At times low voltage of the electrical complexes, premature auricular and ventricular beats and auricular tachycardia developed.

The dietary histories of the patients were usually grossly unbalanced. In the alcoholic group, which in this part of the country represents the majority of cases, the caloric intake was usually high, but the vitamins, especially the B complex, were inadequate. Because beriberi does not develop in all patients consuming the same deficient diet, it is probable that in addition to

the diet certain intrinsic bodily factors are involved. At times poor utilization of food substances played a role in the etiology. In addition to chronic alcoholism, peptic ulcer, chronic diarrhea, surgical resection of the intestine, diabetes, pregnancy, thyrotoxicosis, infectious diseases and psychotic aberration ("food cranks") are prone to predispose to the disease.

The acute form of "wet" beriberi is often precipitated by an increase in the requirement associated with a decreased intake of the vitamin B complex, and thiamin in particular. The vitamin requirement is increased in conditions associated with a high metabolic rate, such as fever, thyrotoxicosis, exercise and a high caloric intake of food. For this reason, after the onset of infectious diseases (pneumonia, malaria typhus, typhoid), persons with faulty nutrition and low vitamin B₁ intake but without symptoms ("presymptomatic" or "subclinical" deficiency) are prone to have fulminating beriberi develop following severe exertion. It is probable that the high mortality rate of alcoholic patients suffering from pneumonia depends in part on nutritional deficiencies.

Since the combination of high caloric and low thiamin intake particularly predisposes to the disease, patients with beriberi are often well nourished, as in the case of the polished rice eaters in the Orient or the alcohol consumers of the Occident. Because man seldom chooses or utilizes his food so that it is deficient in only one factor, patients in addition to manifestations of beriberi not infrequently had symptoms and signs of pellagra and less frequently of scurvy, riboflavin and vitamin A deficiencies. No explanation has been found for the predisposition of patients, apparently on the same deficient diet, to "dry" beriberi in one group and to "wet" beriberi in another.

THE ROLE OF ALCOHOL

Alcohol per se is not considered a primary cause of the cardiovascular manifestations for the following reasons: (a) Chronic alcoholism is a common occurrence, while beriberi is relatively rare. (b) Pharmacologic studies fail to indicate that pure alcohol, without thiamin deficiency, causes cardiovascular damage or polyneuritis. (c) Administration of alcohol and thiamin chloride or vitamin B concentrate improves the clinical manifestations. (d) Chronic alcoholism is apt to be associated with manifestations of other vitamin deficiencies, such as night blindness, scurvy and pellagra.

It is possible, however, as we have pointed out,¹² that alcohol and other nutritional factors play a secondary predisposing role just as a pure carbohydrate diet predisposes to beriberi. Thus Abderhalden and Wertheimer¹³ have demonstrated that, if vitamin B deficient pigeons are fed fatty acids instead of carbohydrates, muscular cramps characteristic of the deficiency do not develop.

The majority of cases of "alcoholic beriberi" occurred among drinkers of whisky and gin, but in a few the condition developed as a result of excessive drinking of beer. The vitamin B content of American beer is low.¹⁴ No instances of beriberi were observed among wine drinkers.

Usually the postmortem studies revealed a moderately or severely dilated heart without coronary or endocardial disease, but in some cases of fatal circulatory

collapse the cardiac dilatation was lacking. In other instances, as reported in 1936, there was myocardial hypertrophy and increase in the weight of the heart. Similarly the microscopic examination revealed varied conditions. In several instances no microscopic changes were present. In others "interstitial edema" or, rather, collagen and "hydropic" degeneration, as described by Wenckebach, was noted. Since these changes were observed by us also in other types of heart disease, they are not to be considered as specific of "beriberi heart." The water content of the myocardium was normal regardless of the presence or absence of myocardial "edema,"¹ suggesting that the intercellular material contained a considerable amount of solids.

DIFFERENTIAL DIAGNOSIS

The individual clinical characteristics of the cardiovascular changes in beriberi, as in other cardiovascular diseases, are not specific. Nevertheless the combination of the clinical manifestations, lack of etiology of other types of heart disease and history of unbalanced diet permit a diagnosis with a fair degree of probability. The combined presence of congestive failure of the circulation and a relatively or absolutely increased rate of the circulation rules out several other types of heart failure. The simultaneous presence of other manifestations of nutritional deficiency disease, particularly polyneuritis, gastrointestinal disturbances, pellagroid cutaneous lesions and a tendency to psychosis make the diagnosis probable. Polyneuritis, often only in a mild form, is usually present in "wet" beriberi. The polyneuritic type of beriberi, however, frequently exists without cardiovascular manifestations. It should be remembered, however, that not every obscure myocardial failure without valvular disease is a "beriberi heart." During the past four years, while attempting to select beriberi with cardiac disease, we have been impressed by the relative frequency of other types of heart disease which, like "beriberi heart," are not as yet commonly recognized by physicians. "Beriberi heart" should be differentiated from diseases of the heart associated with arteriovenous aneurysms, thoracic and spinal deformities, rare cases of cirrhosis of the liver, amyloidosis and xanthomatosis, glycogen disease (Van Gierke), pituitary and ovarian disease, glomerulonephritis, idiopathic postpartum myocardial failure, lupus erythematosus disseminatus, scleroderma heart, Boeck's sarcoid, periarteritis nodosa, thrombo-angiitis obliterans, certain respiratory infections, trichinosis, progressive muscular dystrophy and Friedreich's ataxia. The specific characteristics of these and other myocardial diseases not usually recognized have been discussed elsewhere.¹⁵

The frequency of "beriberi heart" varies considerably, depending on the economic and social level of the population. We have observed more than fifty cases and have collected from hospital records an additional group. In a large charity hospital we noted its occurrence as frequently as once in every 160 medical admissions, but in many of these cases the condition was mild. It is probable that partial deficiencies of thiamin, as determined chemically, will be found to be a relatively frequent nutritional state in this country.

TREATMENT

The response of patients with "wet" beriberi varied considerably. As a rule, patients with "dry" beriberi,

13. Abderhalden, Emil, and Wertheimer, Ernest: Beziehungen des Vitamin B-Komplexes (insbesondere des Vitamins B₁) zum Kohlehydrathaushalt, Arch. f. d. ges. Physiol. 233: 395, 1933.

14. Donovan, P. B., and Hanke, M. E.: The Vitamin-B and G Content of Commercial Beer, Proc. Soc. Exper. Biol. & Med. 33: 538 (Jan.) 1936.

15. Weiss, Soma: Diseases of the Heart and the Aorta Which Are Not Well Recognized, M. Clin. North America 23: 1323 (Sept.) 1939.

cardiac symptoms and electrocardiographic changes improved slowly over a period of weeks with any type of treatment, while patients with massive edema, dilated heart, high venous pressure and enlarged liver usually responded rapidly, particularly if these conditions had existed but a few weeks. Some of the patients improved following rest alone, others after rest, digitalis and mercurial diuretics. But the maximal and most regular benefit was assured by bed rest and massive subcutaneous doses of thiamin up to 20 or 30 mg. three times a day. The size of these doses was determined empirically, and future studies on the fate, storage and elimination of thiamin must determine the rational dosage. Thiamin and vitamin concentrates are effective orally, but because patients with beriberi often suffer from gastrointestinal and liver disorders which may well interfere with the utilization of thiamin it is advisable to use thiamin chloride parenterally in the severe cases. The duration of the condition and the response of the tissues to the deficiency are probably the major factors determining the time of onset of clinical response, which may vary from several days to several weeks following the institution of therapeutic measures. The fact that the myocardium can develop hypertrophy, "hydropic" degeneration and deposition of interstitial collagen indicates that prolonged thiamin deficiency, like other vitamin deficiencies, can change from an easily reversible to an irreversible condition. Rapid improvement is usually associated with diuresis, temporary bradycardia and transient elevation of the arterial pressure. At times the changes in the electrocardiogram may become temporarily accentuated. Diuresis, less dyspnea and contraction of the peripheral arteriolar system were the early manifestations of improvement. Reduction of the size of the heart and disappearance of the alterations in the electrocardiograms occurred days or weeks later.

In some patients the clinical picture of deficiency and the electrocardiographic changes became accentuated for a day or two after the administration of thiamin, following which general improvement occurred. A similar reaction in animals to experimental thiamin deficiency was observed.

Although we have made no special study of the effect of thiamin chloride on polyneuritis, we have had abundant opportunity to compare clinically the effect of thiamin chloride on the nervous and cardiovascular systems. In our experience the effect of thiamin chloride on the cardiovascular system was more pronounced and more rapid. Indeed, the improvement of polyneuritis of severe type was slow and could not be attributed to thiamin chloride alone. There were, however, a few instances of polyneuritis with paresthesias which, after an adequate control period, responded within a few days to thiamin chloride.

Our observations revealed that thiamin chloride is without effect in cardiovascular disturbances other than those of specific deficiency origin. Similarly, only edema of thiamin deficiency disappears after administration of this substance. Toxic side reactions to the thiamin chloride have not been noted even after intravenous administration in doses up to 75 mg. Because patients with beriberi often have other types of deficiencies, attention should be paid to the simultaneous treatment of pellagra with nicotinic acid and other vitamin B complexes, anemia with iron or liver extract and hemorrhagic tendencies with ascorbic acid or vitamin K.

REPORT OF CASES

Since our last report we have observed a number of additional patients suffering from beriberi with polyneuritis and cardiovascular manifestations. The following three cases are summarized here because they represent different forms of the disease:

CASE 1.—A. D., a white man aged 46, admitted on June 19, 1937, to the Boston City Hospital with swelling of the legs and arms of from two to three weeks' duration, had been a chronic consumer of beer and whisky. Analysis of his diet revealed gross deficiency in vitamins, particularly the vitamin B complex. About three weeks prior to admission his body began to swell and there was slight dyspnea on exertion. About thirteen months earlier the patient had had a similar though milder episode of generalized swelling with dyspnea. There was no history of rheumatic fever, syphilis, hypertension or any other organic heart disease. The rest of his history was irrelevant. On examination he was somewhat disoriented as to time and space. He appeared well developed and well nourished. General anasarca was present involving the face. The fundi of the eyes were normal. The left border of the heart

The response of the cardiovascular system to thiamin chloride in case 1.

was 11 cm. from the sternum in the fifth costal interspace. The heart was regular and rapid. The arteries were soft and the arterial pressure was normal or slightly low. Moist rales were present over the bases of the heart. No abdominal organs were palpated. The scrotum was markedly edematous. The patellar and ankle reflexes were diminished, but the superficial sensation was normal. Until the institution of thiamin therapy the specific gravity of the urine was between 1.026 and 1.030 and the urine contained traces of sugar. The hemoglobin concentration was between 74 and 80 per cent with the red cell count from 3.2 to 4.5 million per cubic millimeter. The white blood cell count was between 5,000 and 7,000. Serologic reaction of the blood for syphilis was negative. The electrocardiogram revealed low voltage: T_1 and T_2 were upright, T_3 was flat and T_4 inverted. There was left ventricular preponderance.

In association with Dr. Robert W. Wilkins special studies were carried out, part of which are presented in the chart. The patient was placed on a "vitamin B" free diet by administering specially boiled milk and fruit juices. As indicated on the chart, during the control period the vital capacity the oxygen utilization and the osmotic pressure of the blood were low. The venous pressure was high but the velocity of blood flow and the blood pressure were normal. Following the parenteral administration of 80 mg. of thiamin chloride daily there was a better utilization of oxygen and a slowing of the blood flow, indicating arteriolar constriction. Within forty-eight hours

after administration of the first dose of thiamin chloride there was symptomatic improvement and diuresis developed. It is of particular interest that this diuresis occurred while the osmotic pressure of the blood and the venous pressure remained unchanged. For a time the vital capacity became even lower, indicating increased pulmonary congestion, while the peripheral edema was improving. Within two or three weeks, however, all manifestations of cardiovascular disturbance disappeared. The patient lost 60 pounds (27 Kg.) of edema and the vital capacity of the lungs rose from 2.2 liters to 5 liters. The specific gravity of the urine was between 1.026 and 1.030 before the onset of diuresis and remained between 1.007 and 1.009 during the ten day period of diuresis. At the same time the maximal diameter of the heart changed from 17.5 cm. to 13 cm. with an unchanged thoracic diameter of 34 cm. Following the administration of thiamin chloride a slight degree of transient hypertension developed. This hypertension, as pointed out before, occurs only in the presence of a copious diuresis and is not caused directly by thiamin, because subsequent administration of thiamin fails to induce it again. The patient was discharged from the hospital as cured.

CASE 2.—History.—P. H., a white man aged 31, a laborer, who entered the Boston City Hospital on Oct. 27, 1938, complained of dyspnea and swelling. "My body is all swollen up." For three years the patient had been a heavy consumer of whisky and beer and on numerous occasions had not eaten for days. As stated by his relatives, for weeks before entrance he consumed alcohol and drank soup occasionally but refused food. There were periods in the preceding two years when transient dyspnea and swelling of several days' duration developed. During the three months before his hospitalization the dyspnea and edema became more intense. For one month he had experienced orthopnea, a paroxysmal cough, dyspnea and swelling of the abdomen. For one week the complaints had become unbearable and general anasarca had developed. There was no history of rheumatic fever, syphilis, hypertension or other organic heart disease. The rest of the history was irrelevant.

On examination he appeared to be robust and slightly obese. The face was flushed. There was pronounced dyspnea and a moderate degree of orthopnea. There was no cyanosis, and the skin was warm and covered with perspiration. The vessels of the eyegrounds were normal. The heart was enlarged, 14 cm. to the left of the sternum in the fifth intercostal space. The cardiac impulse was prominent. The pulmonary second sound was accentuated. The heart rate was 120 per minute. No murmurs were heard. There was a protodiastolic gallop rhythm. The arteries were soft. Pistol sounds were heard with each pulsation over the femoral artery. The arterial pressure fluctuated around 90 systolic, 60 diastolic mm. of mercury. No abdominal organs were palpated. Cutaneous sensation was normal. The deep reflexes over the lower extremities were absent. There was a marked degree of generalized edema.

The hemoglobin content was 81 per cent and the red cell count 4.2 million. The white blood cell count was 8,200. Serologic reaction of the blood for syphilis was negative. The nonprotein nitrogen of the blood was 67 and later 56 mg. per hundred cubic centimeters. The carbon dioxide combining power of the blood was 37 volumes per cent. The fasting blood sugar was 100 mg. and the protein 6.3 Gm. per hundred cubic centimeters. The electrocardiogram revealed sino-auricular tachycardia with a rate of 125 per minute. The PR interval was 0.16, the QRS 0.08; T₁ and T₂ were upright, T₃ was inverted and T₄ upright. The QT interval was 0.28. The venous pressure was between 19 and 20 cm. of water and the circulation time thirteen seconds. The dynamics and protein content of the spinal fluid were normal. X-ray examination of the chest revealed an enlarged cardiac shadow with a pronounced degree of congestion of both lungs. The patient was given boiled milk and digitalized within twenty-four hours. The following day the condition remained unchanged. On the evening of October 29 rather unexpectedly the heart rate became faster and early manifestations of circulatory collapse appeared. Twenty mg. of thiamin chloride was administered intramuscularly without avail, and the patient died October 30.

Necropsy.—The lungs were markedly congested. The heart weighed 500 Gm. The myocardium was flabby. All chambers,

but particularly the right ventricles, were dilated. The valves, endocardium, pericardium and coronary vessels were normal. Microscopic examination revealed "interstitial edema" between the myocardial fibers, particularly around the vessels. There was increased collagen also. Vacuolization was present in the conduction bundles. All other structures were normal. The other organs, including the kidneys and blood vessels, were normal.

CASE 3.—History.—J. D., a white man aged 29, a laborer, who entered the Boston City Hospital Sept. 15, 1939, complained mainly of dyspnea of three days' duration and difficulty with walking for a few weeks previous to his hospital entrance. The patient was a chronic consumer of alcohol and his diet was grossly inadequate in vitamins. He had been in the hospital with acute alcoholism in December 1936 and May 1937. On entrance he was disoriented. He was well developed and well nourished. The head, including the eyegrounds, was normal. There was venous engorgement of the neck. The heart was moderately enlarged to percussion. The rate was 110 and regular. No murmurs were heard. The temperature and respiration were normal. The arterial pressure was 116 systolic, 80 diastolic. There was dullness to flatness with rales over the bases of the lungs. Edema was not present. The rest of the examination was negative except for absence of deep reflexes of the lower extremities. Soon after arrival at the hospital the patient became more disoriented, circulatory collapse developed rather unexpectedly and he died three hours after he had been admitted.

Necropsy.—The heart weighed 560 Gm. The cardiac chambers were moderately distended. The lungs were congested and edematous. Microscopic examination revealed a normal myocardium except for slight edema around the blood vessels and between the muscle fibers. There was slight central hemorrhagic necrosis of the liver. The rest of the gross and microscopic examination of the organs, including the kidneys and blood vessels, was negative.

These three cases are examples of different courses of the disease. The first patient suffered from a severe and acute type of beriberi, characterized mainly by right sided heart failure and changes in the peripheral vascular system. Thiamin chloride induced diuresis of 60 pounds, contraction of the arterioles and return to normal of the cardiac and pulmonary functions. The second patient had chronic thiamin deficiency varying in degree over a period of at least three years. He had suffered from several attacks of mild "wet" beriberi. On admission there was a pronounced degree of heart failure of the right and left sided type. Death due to vasomotor collapse occurred with unexpected rapidity, before thiamin could exert its beneficial effect. The heart was not only dilated but also hypertrophied. The third patient had only a mild degree of heart failure, and fulminating fatal vasomotor collapse developed. Again necropsy revealed dilatation and hypertrophy of the myocardium with interstitial edema, hydropic degeneration and necrosis of some of the muscle fibers. Thus, as reported by us before, chronic "beriberi heart" can result in myocardial hypertrophy.

COMMENT

Conclusive evidence of the existence of beriberi with cardiovascular disturbances in this country lends interest to a study and interpretation of the earlier literature. The question may well be raised as to the clinical interpretation of this disease prior to the discovery of its relation to vitamin deficiency.

So keen a physician as Graham Steell¹⁶ remarked in 1906 of the clinical characteristics of dropsy:

Capricious distribution of dropsy is specially apt to occur in cases of the cardiac muscle-failure of beer-drinkers and

16. Steell, Graham: *Textbook on Diseases of the Heart*, Manchester, England, University Press, 1906, p. 18.

of the disease known as beriberi, of both of which diseases, it is curious to note, peripheral neuritis is a clinical feature. . . . Curious special localization of oedema met with, in cases of the kind, have been the scrotum, and together the upper trunk, upper extremities, and scalp and neck, so that oedema simulates that resulting from mediastinal tumour.

I have been told that experienced clinicians in this country have recognized for some time a condition described as "alcoholic myocarditis" and that in the South they were aware that patients with pellagra were poor surgical risks because of the danger of cardiac death and circulatory collapse. In 1924 Magniel¹⁷ described cases of heart disease (le "cœur mou") in association with the consumption of large amounts of alcohol. Patients with this condition had enlarged hearts, gallop rhythm, as a rule obesity and often polyneuritis. May¹⁸ described a similar case in a cook aged 34. Mondon¹⁹ reported a case in which death from delirium tremens occurred at the age of 23, the heart weighing 530 Gm. and interstitial edema being present in the myocardium. In four cases of myocardial disease associated with polyneuritis Hanns and Warter²⁰ found the etiology to be either obscure or attributable to alcohol. In 1933 Campbell and Allison²¹ reported in Ireland a series of eight cases of polyneuritis in which the symptoms of cardiovascular dysfunction were more prominent than the neuritic signs. The nature of these cases is not clear from the report, but the authors raise the question of beriberi. "The cases described here bear some resemblance to the milder types of the disease as it is described in the East. Had these cases been seen in the Orient, it is not improbable that they would have been attributed to that cause. On the other hand, it is open to question whether varied diet of the European could ever become so deficient in vitamin B as to give rise to polyneuritis with cardiac changes." They concluded finally that these cases were probably of an infective rather than of a deficiency origin.

Sporadic instances of heart failure attributed to beriberi in both adults and infants have also been reported in the United States. Kepler²² observed the occurrence of beriberi as a result of a starch diet. Wohl²³ described the polyneuritic form of beriberi in a young diabetic patient who lived on an unbalanced diet. Scott and Herrmann²⁴ reported cardiac manifestations of beriberi among rice workers in Louisiana. Riesman and Davidson²⁵ found beriberi heart in a case after severe voluntary dietary restrictions. In none of the aforementioned publications was the relation of the cardiovascular disturbances to thiamin deficiency appreciated.

Following our investigation reported in 1936, Jones and Sure²⁶ reported a group of eighteen cases of

cardiac insufficiency treated successfully with high vitamin diet and vitamin B₁ concentrate. Hashimoto's case²⁷ is of interest because there were clinical manifestations of both left and right ventricular failure. In this case administration of thiamin chloride intravenously brought dramatic relief from precordial distress, dyspnea and nausea starting within two or three hours. Improvement was progressive thereafter.

Goodhart and Jolliffe²⁸ studied eighty-three alcohol addicts who presented no evidence of chronic cardiovascular disease or renal disturbance. Sixty-five patients of this group had symptoms of dietary deficiency, mainly polyneuritis, and 32.3 per cent had electrocardiographic abnormalities. These authors stated that their observations supported the contention that beriberi in all its manifestations is found among alcohol addicts in this country. They estimated that approximately one third of the alcohol addicts who show vitamin B₁ deficiency in the form of peripheral neuritis present clinical evidence of some degree of cardiovascular dysfunction secondary to this deficiency.

Cossio and Moia²⁹ have reported successful thiamin treatment of cases of beriberi heart occurring in Argentina. In Sweden, Nylin³⁰ observed instances of beriberi heart with marked congestive failure, which responded to thiamin chloride with prompt improvement. Schultz³¹ reported cases of beriberi heart occurring in Finland. Van Bogaert³² presented in detail the case of a young person in Belgium who as a result of alcoholic beriberi developed dilated heart, electrocardiographic changes and circulatory failure. Following the administration of thiamin chloride there was rapid improvement and recovery. In Ungley's case in England a young man with pyloric stenosis and peptic ulcer developed dyspnea and edema.³³ The heart was not enlarged, the circulation time was normal, the venous pressure was elevated, the diastolic pressure was low and changes in the electrocardiogram were present. Administration of thiamin chloride was followed by dramatic improvement and disappearance of all the changes. Jones and Bramwell³⁴ described the occurrence of a classic case of beriberi with severe failure of the circulation in a beer drinker aged 36. Diuresis started twenty-four hours after the administration of thiamin chloride and within two weeks practically all symptoms and signs had disappeared. Yudkin³⁵ studied a case of "wet" beriberi with cardiac manifestations in a man aged 25 whose diet consisted mainly of polished rice. The administration of thiamin chloride effected rapid improvement.

Langeron reported the occurrence of beriberi with cardiac manifestations in France³⁶ and discussed the

relation of these cases to thiamin deficiency. Bickel^{36a} observed cardiac failure as the result of thiamin deficiency among chronic alcoholic addicts and pregnant women in Switzerland. Beneficial response was noted after the administration of thiamin. Dustin, Weyler and Roberts³⁷ analyzed the electrocardiographic changes in several cases in which there were histories of unbalanced diet and clinical evidence of vitamin B₁ deficiency. Their observations concurred with ours in noting an increase in the duration of the electric systole, rapid rate, tendency to low voltage and in most cases flattening of the T wave in leads 1, 2 and 3. During treatment with thiamin chloride, slowing of the heart rate, increase in voltage and varying changes in the ventricular complexes occurred in all cases.

Williams, Mason and Smith³⁸ placed four young women on a diet deficient in thiamin for a period of twenty-one weeks. Anorexia, fatigue, loss of weight, absence of or low free gastric acid, constipation and tenderness of the calf muscles developed. Abnormalities in the electrocardiograms developed in all four cases. The amplitude of all complexes decreased and the daily output of thiamin fell to an unusually low average level of 14 micrograms. Within twelve days after the administration of only 4 mg. of thiamin chloride all defects incident to the previous deficiency had disappeared.

In a recent chemical study of the urinary excretion of thiamin in various clinical conditions, Robinson, Melnick and Field³⁹ observed that in three cases of "alcoholic beriberi," including one of "beriberi heart," the excretion of thiamin was abnormally small. It is of special interest that six of the seven patients with heart failure due to organic heart disease had values indicative of thiamin subnutrition. Likewise it is pertinent that the twenty-four hour urinary thiamin excretion in subjects whose previous dietary intake of thiamin had been adequate, and who ingested an adequate diet on the day of the test, was 90 micrograms or more in all males and more than 60 micrograms in all females but one.

Cardiac complications have been reported in vitamin deficiencies other than thiamin. With the exception of hemorrhagic pericardial effusion in ascorbic acid deficiency, these disturbances should be considered as part of the coexisting beriberi. Thus Feil⁴⁰ described electrocardiographic changes in pellagra. Erdheim⁴¹ observed cardiac dilatation and hypertrophy on post-mortem examination of thirty-one Viennese children who had died with the clinical picture of scurvy in the famine year of 1918. Meixner⁴² observed dilatation and slight hypertrophy of the left ventricle in children suffering from rickets.

EXPERIMENTAL EVIDENCE ON THIAMIN DEFICIENCY AND CARDIAC DYSFUNCTION

The clinical and experimental evidence in man just presented indicates clearly that beriberi, both "dry" and

"wet," is a disease of regular occurrence in America as well as in Europe. The two diseases as observed in the Orient and in the Occident are essentially identical. The dietary history and the clinical response to and reduced excretion of thiamin chloride indicate that in the etiology of "beriberi heart" thiamin deficiency is a primary factor. It is possible that other factors contribute to the disease.⁴³ The relation of thiamin deficiency to heart disease, however, became even more firmly established as a result of recent investigations on animals. In 1930 Drury, Harris and Maudsley⁴⁴ observed a slowing of the heart rate in rats fed on diets deficient in vitamin B₁. Pigeons fed on polished rice also showed bradycardia and in some cases heart block.⁴⁵ Méhes and Péter,⁴⁶ studying the electrocardiograms of rice-fed pigeons, observed that the PR interval was slightly increased and the S and T waves were slightly lower in some of the deficient birds than in the controls. We have studied the effect of thiamin deficiency on rats.³ In all but four or five of the twenty-two thiamin-deficient animals the decrease in heart rate was accompanied by changes in the electrocardiographic complexes, consisting most frequently of an increase in height, flattening, inversion or high or low take-off of the T waves and depression of the S-T segments. From several hours to a day after the subcutaneous administration of thiamin chloride the electrocardiographic changes disappeared in most instances, although occasionally several days was required. The effect of exercise on thiamin deficiency has been studied on four rats. In these animals, allowed to exercise on the running wheel, the cardiac changes were no more marked, of no different character and in only one instance quicker to develop than in the control, nonexercising, thiamin deficient animals. Epinephrine induced cardiac irregularity in some of the thiamin deficient rats. Administration of atropine and section of the vagus nerves did not abolish the cardiac slowing or the electrocardiographic changes produced by thiamin deficiency. The thiamin deficient animals showed increased sensitivity to the toxic effects of strophanthin as borne out by electrocardiographic changes. In a subsequent study we³ concluded that the accumulation of intermediary metabolites plays no significant role in the production of cardiac manifestations in thiamin deficient rats. The finding supports the concept that the manifestation of thiamin deficiency depends on a defect in metabolism rather than on a toxic effect of circulatory metabolites. Large doses of thiamin chloride produced no toxic effects and had little if any influence on the heart rate and electrocardiographic complexes of normal rats and dogs. A vagotonic effect of thiamin on the dog heart could not be definitely established.

De Soldati⁴⁷ has studied the circulatory disturbances in thirteen thiamin deficient dogs. In 90 per cent the heart rate became markedly elevated and in 70 per cent the arterial pressure fell. In eleven dogs on which

electrocardiograms were taken, increased cardiac rate, enlargement of the P waves, changes in the T waves, depression of the S-T segments and prolongation of the Q-T intervals developed. Following administration of thiamin chloride, these changes disappeared. Porto and de Soldati⁴⁸ have studied subsequently the myocardium of four thiamin deficient and two control dogs. The thiamin deficient animals revealed dilatation of the right auricle in all cases and in two of the right ventricle. Intercellular edema and vacuolization of the myocardial conductor and ganglionic fibers were observed. The changes observed by these investigators were similar to those described in human beriberi by Aalsmeer and Wenckebach and by us. These changes are not considered by us as specific, for we were able to demonstrate similar changes in other types of heart disease. Swank and Bessey⁴⁹ induced cardiac failure in pigeons with thiamin deficiency. They observed that if pigeons were slowly depleted of their thiamin on a partially thiamin deficient diet, and if starvation was prevented by tube feeding, dyspnea developed in from three to six weeks. The electrocardiograms showed changes in the QRS complex and in the T waves, together with tachycardia. Administration of thiamin chloride produced rapid recovery in all but the most advanced cases. Post-mortem examination revealed hydropericardium, pulmonary edema and congestion of the lungs and liver. The myocardium of a large percentage of the animals showed focal necrosis. Bradycardia in thiamin deficiency was present only if there was simultaneous starvation. Finally Swank, Porter and Yeomans⁵⁰ found that if a diet partially deficient in thiamin chloride is fed to dogs by tube, they may, after from eight to twelve weeks, develop dyspnea and pulmonary rales and exhibit definite abnormalities of the electrocardiogram. If the animals died during the course of this disorder, at postmortem they showed signs of left ventricular failure (pulmonary congestion and edema). The administration of thiamin chloride promptly resulted in great improvement in the circulation in these animals unless they were actually moribund.

CONCLUSIONS

1. Beriberi both with nervous and with cardiovascular manifestations exists in America and in Europe. Whereas in Oriental beriberi polished rice plays a significant predisposing role, alcohol is the calorogenic substance frequently associated with deficient vitamin intake in the Occident.

2. The clinical features and mechanism of "alcoholic" and "nonalcoholic" beriberi are essentially the same. Similarly, no significant difference could be established between "Oriental" and "Occidental" beriberi.

3. The cardiovascular manifestations of beriberi are related to thiamin deficiency, but other factors may play a secondary role.

4. The evidence now available on the causative relation between thiamin deficiency and cardiovascular dysfunction of beriberi is (a) thiamin deficiency in the diet, (b) decreased thiamin content in the urine, (c) disappearance of the disease after the administration of thiamin chloride, (d) induction of electrocardiographic changes in healthy men consuming a diet lacking only thiamin chloride, (e) induction in animals on a

thiamin deficient diet of cardiac disturbances, including cardiac dilatation, electrocardiographic changes, congestive failure of the circulation and structural changes similar to or identical with those observed in man, and (f) disappearance of the experimentally induced cardiovascular dysfunction in animals after administration of thiamin chloride.

Last year Spies, Bean and Ashe¹ described a syndrome in four persons characterized by "extreme nervousness, insomnia, irritability, abdominal pain, weakness and difficulty in walking," which disappeared dramatically following the intravenous administration of 50 mg. of synthetic vitamin B₆ (pyridoxin). Since this report was published we have observed and treated with identical results twenty similar cases in which there were residual symptoms of nutritional deficiency which could not be relieved with synthetic nicotinic acid, synthetic thiamine hydrochloride or synthetic riboflavin.² In order to obtain more evidence concerning this deficiency state in human beings, we have used the method devised by Scudi, Unna and Antopol³ to investigate the urinary excretion of normal persons taking an adequate diet and of persons with clinical evidence of pellagra, beriberi, riboflavin deficiency and vitamin B₆ deficiency.

MATERIAL AND METHODS

Five normal persons in the laboratory and six patients whose deficiency syndromes were showing clinical improvement were selected as controls. Urine obtained from twelve patients from the Nutrition Clinic of the Hillman Hospital was tested one or more times. These patients had diagnostic evidence of one or more advanced deficiency disease syndromes (nicotinic acid amide nine, pyridoxin four, riboflavin four, thiamine three). Nine of these patients were studied while ambulatory. The other three patients with similar inter-related deficiencies were arbitrarily selected for hospitalization and restricted for three weeks to a deficient diet before any test was done.

The method of Scudi, Unna and Antopol³ was used to determine the level of pyridoxin in the urine. (It

was possible by this method to recover 100 per cent of the material from a control urine sample.) The tests were usually made in the morning, three or more hours after breakfast, since individuals on a good diet show an increased excretion of test producing substances after meals. The patient voided at a specified time and drank one or two glasses of water. The urine was collected exactly one hour later. Fifty mg. of pyridoxin⁴ was then given intravenously, and a sample of urine was collected one hour after the injection. A 5 cc. sample of the urine was diluted with water to 25 or 50 cc. for the test. The blue color produced by this substance was sometimes found in the control specimen, usually in traces only. This value was subtracted from that of the sample for the second hour.⁵

RESULTS

The five normal males excreted an average of 7.9 per cent of the injected pyridoxin in the first hour, with a range of 10.9 to 6.7 per cent. This is in agreement with the finding of 8.7 per cent³ in normal subjects. The six patients without active deficiency disease excreted an average of 8.6 per cent with extremes of 13.2 to 5.4 per cent. In this regard they did not vary from the normal. The group of nine ambulatory patients with evidence of various vitamin B complex deficiencies excreted an average of 0.5 per cent of the 50 mg. of pyridoxin injected, with a range of 1.5 to 0.0 per cent. The four ambulatory patients suspected of having a vitamin B₆ deficiency excreted an average of 0.2 per cent, with a range of 0.4 to 0.0 per cent. One of these was a patient treated successfully with vitamin B₆ last year.¹

The three hospitalized patients were tested at the end of three weeks. Two did not excrete any of the pyridoxin given intravenously, while the other excreted only 0.1 per cent. Most of the patients were definitely improved following the injection of the vitamin.

SUMMARY AND CONCLUSIONS

1. The present study shows that within one hour following the intravenous injection of 50 mg. of pyridoxin the average urinary excretion of this material was 7.9 per cent in normal persons and 8.6 per cent in pellagrins who at the time they were studied did not have active vitamin deficiency. These figures are in agreement with those of Scudi, Unna and Antopol, who observed an average excretion of 8.7 per cent.

2. Nine ambulatory patients with clinical evidence of either pellagra, beriberi or riboflavin deficiency excreted an average of 0.5 per cent of the 50 mg. of pyridoxin injected, with a range of from 1.5 to 0.0 per cent. The four patients in this group suspected of having a vitamin B₆ deficiency showed the lowest excretion of any studied, averaging only 0.2 per cent. It is of interest that one of these patients was treated last year for vitamin B₆ deficiency and was having a recurrence.

3. The three patients with clinical deficiency disease who were hospitalized and restricted to a diet deficient in vitamin B₆ excreted almost none of the injected pyridoxin. This observation indicates that absorption of vitamin B₆ is somewhat dependent on the diet.

4. These results show that vitamin B₆ is important in human nutrition and gives strong support to the hypothesis that clinical deficiency diseases occur not as single entities but as complexities.

5. The administration of acetylsalicylic acid to these patients interferes with this test.

SULFATHIAZOLE

CLINICAL EVALUATION

WESLEY W. SPINK, M.D.

ARILD E. HANSEN, M.D.

MINNEAPOLIS

The successful therapeutic application of sulfanilamide in certain infectious diseases has stimulated investigation of other derivatives of this chemical compound. At the present time there is considerable interest in the thiazole analog of sulfapyridine known as sulfathiazole. This report includes a brief review of the literature concerning the pharmacology, toxicology and therapeutic possibilities of sulfathiazole and presents the results of our clinical experience with sulfathiazole and its sodium salt in the treatment of 128 patients suffering from pneumonia, staphylococcal sepsis and infections of the urinary tract.

Sulfathiazole was first described by Fosbinder and Walter¹ and by Lott and Bergeim.² Van Dyke and his associates³ studied the pharmacology of the drug and concluded that it more rapidly metabolized and underwent less conjugation than sulfapyridine. When the sodium salts of the two compounds were given to mice, they found that sulfathiazole possessed but 65 per cent of the toxicity of sulfapyridine. Long and his co-workers⁴ likewise have stated that sulfathiazole was absorbed more readily and excreted more rapidly than sulfapyridine. They also found that, following the administration of a single dose to human beings, from 80 to 90 per cent of the sulfathiazole was recovered in the urine within twenty-four hours and that, compared with sulfapyridine, definitely less of the excreted sulfathiazole was in the conjugated form. In mice the sodium salt of sulfathiazole possessed an acute toxicity one third greater than that of sulfanilamide but one half that of sulfapyridine. Their observations call attention to a most significant point concerning the toxicity of other thiazole derivatives in that when methyl and phenyl groups were introduced the acute toxicity of sulfathiazole for mice was increased by more than 50 per cent. Reinhold, Flippin and Schwartz⁵ summarized their experience with the compound when given to human subjects as follows: Sulfathiazole was rapidly absorbed from the gastrointestinal tract and rapidly excreted in the urine; following an intravenous injection of the sodium salt, recovery was practically quantitative in the urine; sulfathiazole was poorly absorbed from the rectum; the extent of conjugation was low in most instances; only transitory effects were observed on renal function and the hemopoietic system; the incidence of toxic manifestations was low, vomiting occurring in about 10 per cent of the cases, never severe enough to necessitate discontinuing the drug. More recently Pep-

per and Horack⁶ have brought forth evidence that in the human subject sulfathiazole recrystallized in the kidney tubules, whereas sulfapyridine crystallized most frequently in the renal pelvis and ureters. Because of this tendency for intrarenal precipitation of sulfathiazole, they are of the opinion that renal complications following its use will be more serious than those following the use of sulfapyridine. Their microscopic studies of human kidneys confirmed the earlier work of Gross, Cooper and Scott,⁷ who noted that in white rats sulfathiazole crystallized in the distal collecting tubules.

Turning now to the experimental work concerning the therapeutic possibilities of sulfathiazole, one is confronted by confusing statements, owing in part perhaps to the different technics employed by the various investigators. However, enough uniformity does exist to permit a reasonably intelligent approach to sulfathiazole therapy in certain infections of man. The data of McKee, Rake, Greep and van Dyke⁸ indicate that the therapeutic effect of sulfathiazole in mice was equivalent to that of sulfapyridine for infections due to the pneumococcus, beta hemolytic streptococcus and meningococcus. Both compounds were appreciably effective against the agent of venereal lymphogranuloma but neither affected the viruses of swine influenza or herpes simplex. Long and Bliss⁹ concluded that sulfathiazole as a bacteriostatic agent was as effective as sulfapyridine in broth cultures of Lancefield's groups A, D and G strains of the beta hemolytic streptococcus, *Escherichia coli*, *Staphylococcus aureus*, pneumococcus types I and II and *Bacillus proteus*. Sulfathiazole was slightly less effective in the control of pneumococcal infections in mice, but the difference was partially invalidated because of the more rapid absorption and excretion of sulfathiazole. On the other hand, Lawrence¹⁰ stated that sulfathiazole had a superior inhibitory action on the growth of pneumococci types I, II and III, group A beta hemolytic streptococcus and gonococcus. As a result of the in vitro studies of Rake and McKee¹¹ and of Rammelkamp and Keefer,¹² it would appear that sulfathiazole had greater bacteriostatic activity for *Staphylococcus aureus* than either sulfapyridine or sulfanilamide. Likewise, mice infected with *Staphylococcus aureus* were protected to a greater degree with sulfathiazole than with sulfapyridine.¹³

There is experimental evidence that sulfathiazole will be as effective as sulfanilamide and sulfapyridine, if not more so, in the therapy of infections of the urinary tract. Helmholz¹⁴ found that sulfathiazole had a bactericidal action on strains of *Streptococcus faecalis*,

whereas sulfanilamide or sulfapyridine did not. Sulfathiazole also readily killed strains of *Bacillus proteus*. Neter¹⁵ has confirmed the superior bacteriostatic action of sulfathiazole on *Streptococcus faecalis* (enterococci). Hill¹⁶ concluded that sulfanilamide, sulfapyridine and sulfathiazole had an equal bacteriostatic action on strains of *Staphylococcus aureus*, *Streptococcus faecalis*, *Escherichia coli*, *Aerobacter aerogenes* and *Bacillus proteus*.

Only a few reports are available concerning the value of sulfathiazole in the treatment of human infections. In a preliminary report for the Council on Pharmacy and Chemistry of the American Medical Association, Long¹⁷ was of the opinion that sulfathiazole was about as effective as sulfapyridine in the treatment of pneumococcal pneumonia, and possibly more effective in staphylococcal infections. Fitch¹⁸ reported a case of septicemia and pyemia due to *Staphylococcus aureus* successfully treated with sulfathiazole. Pool and Cook¹⁹ treated fifteen patients having infections of the urinary tract with sulfathiazole and stated that the drug was as efficient as the other sulfanilamide derivatives and more so in infections due to *Staphylococcus aureus*.

They maintained that sulfathiazole was less toxic than either sulfanilamide or sulfapyridine. Flippin, Schwartz and Rose²⁰ treated 100 patients having pneumococcal pneumonia with sulfathiazole and an equal number with sulfapyridine. These two drugs appeared to be equally effective. The incidence and severity of nausea and vomiting were much less in the sulfathiazole group, whereas other toxic manifestations were about equal.

MATERIALS AND METHODS

The types of clinical conditions among the 128 patients treated with sulfathiazole are presented in table 1.²¹ In selecting the patients for therapy an attempt was made in each instance to isolate the biologic agent responsible for the disease.

Patients with pneumonia were divided into two main groups: the first included those with lobar or atypical

21. The sulfathiazole was supplied to us by Dr. George A. Harrcup, director of the Squibb Institute for Medical Research.

pneumonia and the second comprised those having post-operative pneumonia. The sputum was examined bacteriologically in all instances in which it was possible, and if pneumococci were present the Neufeld method was employed in typing. Blood cultures were obtained from all the patients with pneumonia before therapy was instituted.

The following data from the patients were obtained for purposes of therapeutic evaluation of the sulfathiazole: age; time of onset of illness; extent of pulmonary involvement; complicating factors, such as alcoholism, pregnancy and concurrent diseases; serial x-ray films of the lung fields during therapy, and effect of therapy on the clinical course, temperature, pulse, respiration and blood morphology. The oral dosage of sulfathiazole in the treatment of older children and adults with pneumonia consisted of an initial dose of from 2 to 4 Gm. and then 1 Gm. every four hours until the temperature remained normal for forty-eight hours. The dose then was gradually reduced and therapy was discontinued on the fifth to the seventh day. The dosage for infants and small children was 0.25 Gm. per kilogram of body weight a day in divided doses for a period of from

twenty-four to forty-eight hours or until the temperatures dropped to normal; then the dose was gradually reduced and the drug discontinued on the fifth to the seventh day. In the earlier stages of this study we gave from 0.6 to 1 Gm. of sodium bicarbonate with each dose of sulfathiazole, but our later policy, and the one employed at the present time, does not include the administration of the alkali. In three instances type specific antipneumococcus rabbit serum was given in addition to the sulfathiazole. Since postoperative pneumonia is, for the most part, a process of atelectasis with or without an accompanying pneumonitis, sulfathiazole was given in an attempt to abort the spread or development of a pneumonic consolidation. Pneumococci of the higher types were found in the sputum of the majority of these patients. Many could not take medication orally; thus the sodium salt of sulfathiazole was given intravenously. A 5 per cent solution was freshly prepared by dissolving the salt in warm distilled water. Usually 3 Gm. was given as the initial dose and then 1 Gm. every eight hours. Oral therapy was instituted as soon as possible thereafter.

Three patients with pneumococcal bacteremia, mastoiditis and meningitis were treated according to the method of Finland.²² Type-specific antipneumococcus

serum was immediately given intravenously. Shortly thereafter blood was withdrawn and allowed to clot and the serum drawn off and injected intrathecally. The further intrathecal injection of serum containing complement and antibodies depended on the response of the patient. Surgical drainage of the mastoid area was carried out on two of the three patients during the early stages of their illness.

Two groups of patients with staphylococcal infections were treated with sulfathiazole. The first group of twenty-one patients was that presenting localized lesions without demonstrable bacteremia and included such conditions as carbuncles, postoperative wound infections, decubitus ulcers, osteomyelitis, otitis media and empyema. Staphylococci were obtained from the lesions of all these patients. In some cases the topical application of sulfathiazole was employed. The second group consisted of fifteen patients having staphylococcal septicemia. The dose of sulfathiazole was essentially the same as that used in the therapy of patients with pneumonia, except that the drug was given over a longer period of time. Blood cultures were obtained before, during and after sulfathiazole therapy.

Twenty patients with infections of the urinary tract were treated in cooperation with Dr. C. D. Creevy, chief of the division of urology. We were particularly interested in infections due to *Bacillus proteus*, *Escherichia coli* and the staphylococcus. Carefully catheterized specimens of urine were cultured before therapy was begun and again at various intervals after sulfathiazole therapy had been discontinued.

The concentration of the free and conjugated forms of sulfathiazole in the blood were determined²³ by the method of Marshall and Litchfield.²⁴ In the group with infections of the urinary tract, the concentration in the urine was quantitated.

LOBAR AND ATYPICAL PNEUMONIA

The results of sulfathiazole therapy of thirty-three patients with lobar or atypical pneumonia are presented in table 2. Attempts to type pneumococci in the sputums of nine of these patients were unsuccessful because they were first seen very early in the course of illness and were not coughing up any material. Bacteremia was demonstrated in only one case. Death of but one of these thirty-three patients occurred, and this subject was an elderly man who died three months after the onset of pneumonia from multiple lung abscesses. He was afflicted also with pernicious anemia. Type specific antipneumococcus rabbit serum was used in three cases in addition to the sulfathiazole. Of these three patients, one had a type I bacteremia and pneumonia and in addition severe diabetic acidosis and a furuncle. His temperature failed to decrease below 101 F. after twenty-four hours of sulfathiazole therapy, although bacteremia was no longer present. He therefore was given 100,000 units of type I antipneumococcus serum, which was followed by a prompt fall in temperature. Subsequently empyema due to type I pneumococci developed and was successfully drained. The second patient receiving serum had a type III pneumonia and a moderate degree of icterus. She responded poorly to sulfathiazole so 200,000 units of specific antipneumococcus serum was given. Following this the patient

23. The determinations were performed under the direction of Dr. G. T. Evans, director of laboratory service, University of Minnesota Hospitals.
24. Marshall, E. K., Jr., and Litchfield, J. T., Jr.: Determination of Sulfanilamide, *Science* 88: 85 (July 22) 1938.

slowly improved, but at the time she left the hospital several weeks later she had residual lung abscesses. The third patient had a type V pneumonia and was in the last trimester of pregnancy. Her temperature failed to decrease after adequate doses of sulfathiazole, so she was given 53,000 units of specific antipneumococcus rabbit serum. Shortly thereafter her temperature became normal.

The effect of sulfathiazole on the clinical course of pneumonia was less dramatic than that which we have experienced with the use of sulfapyridine. The temperature curves showed a slower and more gradual approach to normal following the administration of sulfathiazole. Although the number of cases that we have presented is small, the end results with sulfathiazole compare very favorably with sulfapyridine, and the patients as a whole tolerated the former drug much better. Toxic manifestations were less frequently encountered in this group of patients than in a comparable group treated with sulfapyridine. Vomiting occurred in only one instance. The drug had to be discontinued in one case because of the appearance of an erythema nodosum-like cutaneous lesion with drug fever on the ninth day of treatment. It is of interest that one patient who had received sulfapyridine five months previously for pneumonia had at that time an extensive dermatitis. When this patient was given sulfathiazole a papular eruption appeared on her arms shortly after therapy was instituted, but this medication was continued for several more days with no untoward reactions.

POSTOPERATIVE PNEUMONIA

Of the twenty-two patients having postoperative pneumonia treated with sulfathiazole, twelve were given the sodium salt intravenously. None of the patients had a bacteremia due to the pneumococcus; however, *Escherichia coli* was demonstrated in the blood of one patient. Although two of the patients died, death was attributable to causes other than the pneumonia. The toxic manifestations following the use of the sodium salt of sulfathiazole were minimal, although one patient had a gross hematuria with no other evidence of kidney dysfunction. A further discussion of sulfathiazole in the treatment of postoperative pneumonia will be presented elsewhere.

PNEUMOCOCCIC MENINGITIS

Three patients with pneumococcic meningitis were treated with sulfathiazole and specific antipneumococcus rabbit serum. Because there are no reports available in the literature concerning the value of sulfathiazole in the therapy of pneumococcic meningitis, the course of events in the illness of each of these patients is presented:

CASE 1.—M. S., a housewife aged 39, entered the service of Dr. Horace Newhart of the University Hospitals on March 4, 1940, in a comatose condition. Ten days before, an infection of the upper respiratory tract had developed, followed by a bilateral earache, headache, stiff neck, nausea and vomiting, and finally coma. The left ear drum was injected and there was tenderness over the right mastoid area. The neck was held in rigid hyperextension; Kernig's and Brudzinski's signs were positive. Lumbar puncture showed the spinal fluid to have a pressure of 18 mm. of mercury; 600 cells were present with 94 per cent polymorphonuclear leukocytes and 4 per cent monocytes; sugar was less than 15 mg. per hundred cubic centimeters, protein 1.2 Gm. per hundred cubic centimeters. Type III pneumococci were isolated from cultures of the spinal fluid, blood and exudate of both ears.

Shortly after admission the patient was given 175,000 units of type III antipneumococcus rabbit serum intravenously. This was followed by a lumbar puncture, drainage of the fluid and the intrathecal introduction of specific type III pneumococcus antibody and fresh human serum. Thereafter daily drainage of spinal fluid was carried out and the fluid replaced with human serum and type III antipneumococcus rabbit serum. Sulfathiazole was administered orally through a nasal tube, and on two occasions she was given the sodium salt of sulfathiazole intravenously. The course of the patient's illness is depicted in chart 1. The blood concentration of sulfathiazole was maintained at high levels throughout her illness. After the first day, repeated cultures of the spinal fluid and blood remained sterile. However, her condition became worse on the fifth day, when she had marked abdominal distention and severe diarrhea. She became cyanotic, the Cheyne-Stokes type of respiration developed and she died March 13. At necropsy there was little involvement of the meninges. Death was attributed to an extensive and severe peritonitis.

The following case is of exceptional interest because on two different occasions the patient entered the hospital suffering from meningitis. The first attack was due to a beta hemolytic streptococcus and the second to a type III pneumococcus. The patient recovered completely from both infections.

CASE 2.—W. V., a boy aged 6 years, was first seen in the University Hospitals on Dec. 23, 1938. About ten days before

Chart 1 (case 1).—Type III pneumococcus meningitis unsuccessfully treated with sulfathiazole.

he had complained of a bilateral earache, following which the ears began to drain. Subsequently fever, projectile vomiting and a stiff neck developed and he appeared dehydrated and irrational. The tympanum of each ear was thickened, but no exudate was seen. The neck was rigid, the thighs were held in flexion, and Kernig's and Brudzinski's signs were present.

Bilateral myringotomy revealed no exudate. An x-ray film of the left mastoid area showed evidence of an acute inflammatory process. Cultures of venous blood remained sterile. Examination of the spinal fluid showed it to be under increased pressure. There were 5,300 cells with 69 per cent polymorphonuclear leukocytes and 31 per cent monocytes. A pure culture of beta hemolytic streptococci was isolated from the fluid. The protein level was 171 mg. per hundred cubic centimeters. The course of his illness is illustrated in chart 2. Following the administration of the sulfanilamide the spinal fluid cultures remained sterile and he progressively improved. He left the hospital Jan. 17, 1939.

He entered the University Hospitals the second time on March 1, 1940. He had been in good health since his previous discharge from the hospital until ten days before the present entry, when he contracted an infection of the upper respiratory tract. This was followed by pain in the left ear, headache, nausea and vomiting, and stupor. On examination the patient was stuporous and had a left facial paralysis. The ears showed slight, purulent discharge from the left and edema of the tympanum on the right. His neck was rigid; the reflexes of the extremities were hyperactive; Kernig's sign was present. Lumbar puncture yielded spinal fluid that was slightly cloudy. There

were 7,200 leukocytes, of which 58 per cent were polymorphonuclear neutrophils and 42 per cent monocytes. There were 221 mg. of protein per hundred cubic centimeters. Type III pneumococci were isolated from the spinal fluid and the blood stream. He was given an initial dose of the sodium salt of sulfathiazole intravenously and then the drug was administered orally. Following this, 136,000 units of type III antipneumococcus rabbit serum

Chart 2 (case 2).—Beta hemolytic streptococcus meningitis successfully treated with sulfanilamide.

clinical course of this patient. It is important to note the low levels of sulfathiazole in the spinal fluid as compared to the concentrations in the blood. The patient left the hospital March 28 in good condition and has remained well.

CASE 3.—I. M., a girl aged 1 year, who entered the University Hospitals on April 1, 1940, had had an injection of the upper respiratory tract six weeks prior to this, complicated by a bilateral otitis media. Five days before entry her left eye became swollen and reddened. Generalized convulsions were observed. Her ears began to drain spontaneously. She was febrile and her condition became progressively worse. Sulfanilamide had been given without any improvement. On physical examination the child appeared acutely ill. A right-sided facial paralysis and a ptosis and discoloration of the left eye were observed. The tympanum of each ear was inflamed. The neck was held in rigid extension. Respiration was of the Cheyne-Stokes type. The reflexes of the extremities were all increased and Kernig's sign was present. Type XVIII pneumococci were cultured from both the blood and the spinal fluid. The spinal fluid had a ground glass appearance and was under a pressure of 40 mm. of mercury. Examination revealed only 9 monocytes, protein was 162 mg. per hundred cubic centimeters and sugar was less than 15 mg. per hundred cubic centimeters. Sulfathiazole was administered intravenously and then orally through a nasal tube. A total of 40,000 units of type XVIII antipneumococcus rabbit serum was given intramuscularly and intravenously. Specific serum and human complement were administered intrathecally. Subsequent blood cultures remained sterile, but type XVIII pneumococci were constantly recovered from the spinal fluid. Failure to sterilize the spinal fluid may be explained partly on the basis that at times there was evidence of a partial block of the spinal canal. It is of interest that the levels of free sulfathiazole in the blood were 7.8, 8.9, 4.3, 7.5, 19.9 and 1.2 mg. per hundred cubic centimeters, while simultaneously the concentrations in the spinal fluid were 4.4, 5.4, 1.8, 2.7, 2.1 and 2.7 mg. per hundred cubic centimeters. The patient's condition became progressively worse and she died April 20. Postmortem examination revealed evidence of an extensive basilar meningitis and pneumonia.

MISCELLANEOUS PNEUMOCOCCIC INFECTIONS

The following case is of interest because of the unusual nature of the disease process and the successful use of sulfathiazole in the presence of acute glomerular nephritis:

CASE 4.—G. S., a boy aged 12 years, contracted right otitis media three weeks before entry to the hospital. He had fever and swelling of the tissue over the right mastoid area. Two

weeks after the onset of his illness there appeared a generalized edema of the face and extremities, accompanied by vomiting. The night before entry there occurred a sudden onset of severe dyspnea. When first seen in the hospital, he was cyanotic, irrational and extremely dyspneic. His temperature was 106 F. There were loud bubbling moist rales throughout both lung fields. The heart was enlarged to the left on percussion. The rate was 160 per minute with a gallop rhythm. The blood pressure was 120 mm. of mercury systolic and 90 mm. diastolic. The external jugular veins were engorged and pulsating. The abdomen was distended and the liver enlarged. Urinalysis showed a large trace of albumin, and the sediment contained numerous granular and hyaline casts, erythrocytes and leukocytes. The blood urea nitrogen was 29.3 mg. per hundred cubic centimeters. Type XII pneumococci were isolated from the blood. X-ray films of the chest revealed marked pulmonary edema and generalized enlargement of the heart. It was apparent that the patient had pneumococcal bacteremia probably originating from the otitis media, acute glomerular nephritis with nitrogen retention, and acute cardiac failure with pulmonary edema. Shortly after admission a venesection was performed and 450 cc. of blood was withdrawn. Then 50 cc. of a 50 per cent solution of sorbitol with 0.24 Gm. of aminophylline was given intravenously, following which considerable improvement was noted. Because of the pneumococcal bacteremia, 4 Gm. of the sodium salt of sulfathiazole was given intravenously and eight hours later 2 Gm., a similar dose being repeated in another eight hours. His temperature dropped from 106 F. to normal within twenty-four hours and remained there. Blood cultures remained sterile. He continued to receive sulfathiazole orally after the foregoing intravenous therapy for seven days. His improvement continued and he left the hospital May 6, 1940. When seen one month later he was in good health with no residual evidence of his having had nephritis.

Another unusual pneumococcal infection which was treated is reported in case 5:

CASE 5.—A boy aged 7 years fell and received a compound fracture of the ulna and radius of the left arm twelve days before admission to the hospital. The tissue overlying the fracture site became infected and 150 cc. of purulent material was aspirated from a localized abscess. This contained a pure culture of type V pneumococci. Blood cultures were sterile. Pneumococci were not isolated from cultures of material taken from the nose and throat. The arm was immobilized and the area treated with hot packs. At the same time sulfathiazole

Chart 3 (case 2).—Type III pneumococcus meningitis successfully treated with sulfathiazole and type III antipneumococcus rabbit serum.

was administered orally for five days. Coincident with this therapy, the infection subsided and on x-ray examination four weeks later callus formation was abundant. His general condition was good, and there was normal function of the hand when the patient was seen six weeks later.

STAPHYLOCOCCIC SEPSIS

In the group of thirty-six patients who had staphylococcal sepsis there were twenty-two having localized lesions without demonstrable invasion of the blood stream by organisms. The lesions included postopera-

tive wound infections, otitis media and mastoiditis, empyema, suppurative arthritis, carbuncles, decubitus ulcers, osteomyelitis and subcutaneous abscesses but did not include any infections of the urinary tract. In treating these patients we were fully aware of the inhibitory effect of bacteria, leukocytes and necrotic material on the bacteriostatic action of sulfathiazole. Our object in treating them was not directed primarily at the abscessed tissue but at preventing spread of the infection to healthy tissue and possible invasion of the blood stream. Two methods of therapy with sulfathiazole were employed: One was to administer the drug orally, endeavoring to maintain a constant concentration of 5 mg. per hundred cubic centimeters of free sulfathiazole in the blood. This therapy was continued for only a few days in some cases and for several weeks in others. The second method was to apply sulfathiazole locally to the diseased tissue. For this purpose we used pure sulfathiazole crystals and sprinkled them into the wound; or the crystals were suspended in sterile distilled water, cod liver oil or physiologic solution of sodium chloride and the suspension then introduced into the infected area. The oral administration of sulfathiazole often was combined with the topical application of the chemical. One of us (W. W. S.) carried out this phase of our sulfathiazole studies with Dr. John R. Paine of the department of surgery, and a more complete report is forthcoming concerning the methods and results. In brief, the topical application of sulfathiazole entails adequate drainage and immobilization of the infected area, frequent irrigations with mild antiseptic solutions to eradicate purulent and sloughing material, saturation of the wound with sulfathiazole, and, in some instances, the administration of sulfathiazole orally. In the majority of cases treated in this manner but little of the sulfathiazole appeared in the circulating blood. The results have been highly satisfactory and merit further investigation.

Our most satisfactory clinical results with sulfathiazole occurred in the group of fifteen patients with staphylococcic septicemia. All these patients recovered. One patient died subsequently from leukemia. Since we have treated a comparable number of patients having staphylococcic septicemia with sulfapyridine, a detailed report is in preparation describing our clinical experience with chemotherapy in this type of infection. So far as the use of sulfathiazole is concerned, the drug was administered orally, when possible, so that a concentration of from 4 to 5 mg. of free sulfathiazole was maintained in the blood. It is doubtful whether higher levels are necessary. It should be emphasized that in conjunction with the exhibition of sulfathiazole it is imperative that adequate drainage of the focus or foci be carried out promptly. The length of time sulfathiazole therapy should be continued is dependent on the individual case. It is our belief at the present writing that sulfathiazole is the most effective therapeutic agent in the treatment of staphylococcic septicemia.

INFECTIONS OF THE URINARY TRACT

A majority of the twenty patients who had urinary infections were treated in cooperation with Dr. C. D. Creevy. The drug was given a severe therapeutic test in some of these instances. Many of the patients had been treated unsuccessfully with other therapeutic agents, including sulfanilamide and sulfapyridine. Furthermore, some of the patients had partial obstruction of the urinary tract. The offending organisms included

alpha hemolytic streptococcus (faecalis and viridans), Staphylococcus albus and aureus, Bacillus proteus and Escherichia coli. Dr. Creevy informed us that in his experience infections of the urinary tract due to Bacillus proteus were most resistant to all forms of therapy. The dose of sulfathiazole used in these cases was 1 Gm. from four to six times a day for from seven to ten days. Definite clinical improvement was obtained in thirteen of the twenty cases. It may be of significance that the highest incidence of toxic reactions from sulfathiazole was in this group of patients with infections of the urinary tract. It would appear from our experience with this group that sulfathiazole may have a definite place in the therapy of infections of the urinary tract, particularly infections due to staphylococci, alpha hemolytic streptococci, Bacillus proteus and, in some instances, Escherichia coli.

MISCELLANEOUS INFECTIONS

Table 1 lists the nature of the miscellaneous infections treated. No clinical improvement was obtained by two patients with subacute bacterial endocarditis due to

Chart 4.—Recovery of a man aged 55 from septicemia due to alpha hemolytic streptococci (*Streptococcus viridans*) following administration of sulfathiazole.

Streptococcus viridans. The blood stream of two patients was cleared of *Escherichia coli* following the use of sulfathiazole. In one the primary focus was in the urinary tract, and in the second the bacteremia followed an enterostomy performed because of an acute intestinal obstruction. Although only four patients having gonococcic arthritis were treated with sulfathiazole, the clinical results were less satisfactory than those obtained with equivalent doses of sulfanilamide and sulfapyridine. In two of these four cases there was some clinical improvement following adequate doses of sulfathiazole, but the improvement was more marked when sulfanilamide was given subsequently. One elderly patient with a severe infection due to beta hemolytic streptococci did not respond to sulfathiazole therapy. A patient with septicemia due to alpha hemolytic streptococci (*Streptococcus viridans*) was of particular interest. He had had daily chills and fever for three weeks, and streptococci had been isolated from his blood on three occasions. At one time there were 167 colonies per cubic centimeter of blood. It was the consensus of the consulting staff that the primary focus was in the biliary tract. Sulfanilamide was given with but little clinical improvement. Sulfathiazole was then administered, following which the patient's temperature approached normal and blood cultures became sterile. When the sulfathiazole was discontinued he again had fever, and streptococci were recovered from the blood stream. After resumption of sulfathiazole therapy, his

fever subsided and blood cultures again became sterile. He improved rapidly and has been in good health ever since. The clinical course in this case is illustrated in chart 4.

ABSORPTION, EXCRETION AND CONJUGATION

From the observations made in these studies, we are able to conclude that sulfathiazole was absorbed less readily than sulfanilamide and more readily than sulfapyridine. When patients were given sulfanilamide orally in divided doses, it was observed that higher concentrations could be obtained and maintained in the blood than could concentrations of sulfathiazole when the same patients were given sulfathiazole at another period. It should be pointed out, however, that this difference is more apparent than real, since sulfathiazole is excreted more rapidly than sulfanilamide. In other words, sulfathiazole may be absorbed to the same extent as sulfanilamide, but there might be some difficulty in maintaining equivalent concentrations in the blood because of this difference in excretion. Sulfathiazole was eliminated from the body much more rapidly than either sulfanilamide or sulfapyridine, and practically all of the drug that was absorbed could be recovered quantitatively in the urine. We have noted

TABLE 3.—Toxic Manifestations Encountered in Group of One Hundred Patients Treated with Sulfathiazole

Manifestation	No. of Patients
Dermatitis	9
Nausea and vomiting	6
Nitrogen retention and oliguria.....	1

Drug fever	2
Burning and itching of the eyes.....	2
Injection of conjunctivas	1
Anemia	1

in some cases that, following the oral administration of sulfathiazole, the urine appeared quite cloudy, and a white sediment formed when the urine was allowed to stand at room temperature for several hours. This sediment consisted almost entirely of sulfathiazole crystals. It was observed that when a single dose of sodium sulfathiazole was given to a patient intravenously a large amount of the drug was excreted within fifteen hours. An analysis of several hundred determinations of the concentration of the free and conjugated forms of sulfathiazole in the blood of patients permits us to conclude that the average amount of conjugated sulfathiazole is about 20 per cent. In two cases 50 per cent of the drug was present as the conjugated form. It is difficult to evaluate the amount of drug that a given patient will conjugate when the single dose method is used, since we have observed that the degree of conjugation varies when several doses are given over a period of several hours or days. The degree of conjugation is somewhat greater than that which is encountered following the administration of sulfanilamide; on the other hand, it is definitely less than the amount of sulfapyridine that is usually conjugated.

TOXICITY

The toxic manifestations from sulfathiazole are based on observations made on 100 patients (table 3). The most common evidence of toxicity was a cutaneous eruption, which usually appeared after the drug had been given for several days. It was a maculopapular type

of eruption, most prominent over the extremities. In four of the cases the lesion simulated erythema nodosum very closely. In one of these drug therapy was discontinued and the lesion disappeared. After a lapse of several days the same doses of sulfathiazole were given without any further cutaneous eruption.

Nausea and vomiting occurred in six cases, but in only one was it severe enough to warrant discontinuing further administration of the drug. The degree and incidence of this complication were definitely less than with sulfapyridine therapy. Sodium sulfathiazole has been given intravenously in thirteen cases without producing any evidence of nausea or vomiting.

One patient suffered from oliguria and nitrogen retention after receiving 27 Gm. of sulfathiazole by mouth in five and one-half days. He recovered completely. Gross hematuria was encountered once following the intravenous administration of sodium sulfathiazole. This patient had no other evidence of kidney dysfunction.

Two patients complained of burning and itching of the eyes while receiving sulfathiazole. This promptly subsided when therapy was stopped. One other patient had a marked injection of the conjunctiva of one eye with a slight amount of purulent discharge while receiving the drug.

Anemia of a moderate degree was noted in only one instance. In no instance was there a depression of the leukocytes or granulocytes that could be attributed solely to the drug.

SUMMARY

In the course of these studies on 128 subjects suffering from a variety of infections we have endeavored to compare sulfathiazole with sulfanilamide and sulfapyridine as regards its pharmacology, toxicology and therapeutic effectiveness. Comment has already been made on its absorption and excretion. Of considerable importance is the question of toxicity. Thus far, in our experience, sulfathiazole appears to be no more toxic than either sulfanilamide or sulfapyridine. In fact, the troublesome nausea and vomiting that not infrequently follow the administration of sulfapyridine are not so commonly encountered when sulfathiazole is used. The incidence of dermatitis, however, is greater following the use of sulfathiazole than either sulfanilamide or sulfapyridine. As regards the therapeutic phase of the study, it appears that sulfathiazole has the same value as sulfapyridine in the treatment of pneumococcal pneumonia. Sulfapyridine seems to cause a more abrupt fall in temperature than sulfathiazole; however, there is some evidence that sulfapyridine may have a nonspecific antipyretic effect. When sulfapyridine was given to febrile patients who had fever not due to an infectious agent a prompt decrease in the temperature was noted, which in turn was followed by a rise when the drug was omitted. This was especially true in a case of lymphatic leukemia in which there was no evidence of an infection. Whether or not sulfathiazole is as valuable as sulfapyridine in the therapy of pneumococcal meningitis is dependent on further investigation, as is also the topical application of sulfathiazole for localized staphylococcal lesions. However, there is no doubt that sulfathiazole is more effective than sulfapyridine in the treatment of staphylococcal septicemia and appears to be the best therapeutic agent available for this infection at the present time. Sulfathiazole appears to be of especial value in the treatment of infections of the urinary tract

due to *Bacillus proteus*, alpha hemolytic streptococci, *Escherichia coli* and staphylococci. Its exhibition may result in sterile cultures of urine when sulfanilamide therapy has been ineffective.

CONCLUSIONS

1. In thirty-three cases of pneumococcic pneumonia, sulfathiazole appeared to be fully as effective a therapeutic agent as sulfapyridine.

2. Recovery of one of the three patients having pneumococcic meningitis occurred following administration of sulfathiazole and type specific serum.

3. Fifteen consecutive patients with staphylococcic septicemia were successfully treated with sulfathiazole. (One patient died subsequently of leukemia.)

4. The results of the use of sulfathiazole in the treatment of twenty cases of infection of the urinary tract, many of which had been refractory, suggested that this drug may be a useful adjunct in the therapy of infections of the urinary tract, particularly those due to staphylococci, *Bacillus proteus*, alpha hemolytic streptococci and *Escherichia coli*.

5. Sulfathiazole was readily absorbed and quickly excreted in the urine, while the degree of conjugation was less than that occurring with sulfapyridine.

6. Less nausea and vomiting accompanied the use of sulfathiazole when compared with sulfapyridine; however, dermatitis was more frequently encountered with sulfathiazole than with either sulfanilamide or sulfapyridine.

Clinical Notes, Suggestions and New Instruments

LOCAL ANAPHYLACTIC (ARTHUS?) PHENOMENA FROM PARENTERAL INJECTIONS OF HISTAMINASE

SIGMUND S. GREENBAUM, M.D., PHILADELPHIA

Typical examples of local anaphylaxis are rarely observed in human beings.¹ Although reported in connection with injections of vaccines (rabies, typhoid), antitoxin and toxin-antitoxin, this is the first report of a local anaphylactic reaction developing after injections of histaminase.²

Local anaphylaxis (the Arthus phenomenon) is the "inflammatory reaction which occurs when an animal immunized against a protein is reinjected with the same antigen—it is caused by the presence of an antibody in the blood stream and tissues of the immunized animal and occurs when antigen and antibody meet in tissues" (Opie). It is by most sharply differentiated from the Schwartzman phenomenon. It is possible for such antibodies to be present only in the tissues, i.e. tissue sensitization without the presence of antibodies in the blood stream. It is perhaps on this basis that the passive transfer test performed with the serum obtained from my first patient was negative—in fact the control showed more definite erythema than the presumably sensitized site of injection of the histaminase.

The time interval in case 1 (approximately twenty-eight days) between the first and second injection was of interest and may account for the more marked local reaction than that occurring in case 2.

At the present writing, eight other patients within the past six weeks have received at intervals of three or four days injections of histaminase without untoward reactions of any significance.

1. Vaughan, W. T.: *Practice of Allergy*. St. Louis, C. V. Mosby Company, 1939, p. 793.

2. The histaminase used was the product of the Winthrop Chemical Company: T 360. The ampule contains 2 units of histamine hydrochloride detoxifying units in the form of a dry sterile powder (renal and pig mucosal tissue), which for injection purposes is suspended in about 2 cc. of sterile physiologic solution of sodium chloride.

REPORT OF CASES

CASE 1.—A. L., a housewife aged 39 with acne vulgaris, was given into the left arm over the deltoid region on Feb. 19, 1940, a subcutaneous injection of histaminase. The day after this injection the patient left, unexpectedly, for Florida and did not return to the office until March 18, at which time she received another injection—the same dose of histaminase but in the subcutaneous tissue over the right deltoid. Within eight hours the arm became swollen from the shoulder to the elbow and there was some limitation in the movement of the right elbow. There was no elevation of temperature and the patient felt well except for a sense of tenseness due to the marked edema in the right arm. The next morning the arm was markedly swollen and the skin tense and hot over the area indicated. There was moderate tenderness and slight pain. There was no fever and no axillary adenitis. On the inner surface of the arm was an area of erythema the size of the palm of a hand but the remainder of the skin over the swollen arm showed only the changes incident to the tense, nonfluctuating subcutaneous edema. The patient was advised to use compresses of hot magnesium sulfate (a tablespoon to a quart of water) continuously. On the morning of the 20th she was seen again. The temperature the evening before had gone to 99 F. but on this morning was normal. A portion of the erythematous area the size of a silver dollar (38 mm.) had undergone wheal formation (at which site there was moderate pruritus) the night before but was now gone. A localized area of urticaria had actually developed. The swelling was moderately but definitely less, but the entire arm now itched and she was advised to continue the hot applications of magnesium sulfate. By the morning of March 22 the edema had disappeared to a marked degree. There was a mild, slightly tender axillary adenitis. There was some induration at the site of the injection. One week later I removed 10 cc. of blood and the next day started, with the serum, a passive transfer test. One tenth cc. of the serum was injected intracutaneously into the flexor skin of the left forearm; four days later a slightly smaller amount of histaminase solution was injected at the site of the serum injection and a control injection given into the flexor skin of the right arm. No reaction occurred although the patient was observed for one week.

CASE 2.—M. E., a nurse aged 35 with a deep form of acne vulgaris, was given an injection, March 15, 1940, subcutaneously into the left thigh. Four days later she received a second injection, the same dose, subcutaneously into the right thigh. Seen three days later the patient stated that swelling had developed at the site of the second injection twenty-four hours after it had been given. When I saw her the skin over the injected area had assumed an erythematous-urticarial appearance. The erythematous patch was an area 8 by 15 cm. and pruritic; twenty-four hours later the redness was gone, as was the swelling, but moderate pigmentation was present. On March 24 the patient was seen again and given one half the dose (i. e. one detoxifying unit) subcutaneously into the left thigh well above the site of the first injection. That night some redness developed over the injected area and from 2:30 to 6 a. m. severe abdominal cramps, nausea and diarrhea developed. She was so weakened that she remained in bed the entire following day. The patient, a dietitian at the hospital, did not attribute her gastrointestinal upset to any food she had eaten as the same food had been served to about 200 other hospital employees and nurses without any of them having any ill effects. March 29 the patient was given a fourth injection of 0.5 cc. of the solution (i. e. one fourth the dose). There was no untoward reaction. April 2, she was injected with one half the dose, and four days later, since there had been no reaction, a full dose was given and was well tolerated.

COMMENT

An interesting point in both cases is that the histaminase itself set up, albeit only locally, an urticarial type of reaction. Histaminase has been advised as a beneficial agent in urticaria. Can a substance producing an urticarial reaction be of value in the treatment of a similar objective symptom which has so many known causes or is one to believe in *similia similibus curantur*?

320 South Eighteenth Street.

Special Article**THE PHARMACOPEIA AND THE
PHYSICIAN****THE DRUG THERAPY OF CARDIAC
ARRHYTHMIAS**

ROBERT L. LEVY, M.D.

NEW YORK

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed.

Irregularity of the heart beat is observed usually in association with organic cardiac disease but occurs not infrequently as a functional disturbance in the absence of structural lesions. It is due either to faulty initiation of the cardiac impulse or to its defective conduction through the heart. The arrhythmia may be transient or permanent. Effective treatment depends primarily on recognition of the cause. Drug therapy often brings about marked clinical improvement and, on occasion, may save life.

The use of medicinal remedies is not indicated in every disorder of rhythm or under all circumstances. For example, sinus irregularity, often marked in children, is of no pathologic significance. Premature contractions due to tobacco disappear when smoking is stopped. Auricular fibrillation, occurring in the course of hyperthyroidism, may terminate spontaneously after subtotal thyroidectomy. Five of the more important arrhythmias have been chosen for consideration because in each, as a rule, appropriate treatment with drugs is beneficial.

PREMATURE CONTRACTIONS

Many patients experience no discomfort from premature beats and are unaware of their occurrence. Others complain of palpitation or, more rarely, of precordial pain. This arrhythmia has been observed over a period of many years in persons in whom symptoms or signs of organic heart disease have not developed. The ectopic focus may be situated in auricles, junctional tissues or ventricles. Localization of the point of origin, possible only with the aid of the electrocardiograph, is immaterial for purposes of therapy. But an etiologic diagnosis is essential.

If the heart muscle is irritated by a toxic agent it is necessary only to eliminate the cause. The use of coffee, tea or tobacco can be discontinued. If the gallbladder is infected, its surgical removal is indicated. Recovery from nervous fatigue is aided by a respite from customary activities. Any drug, particularly digitalis, must be stopped if it is poisoning the myocardium.

Premature beats associated with emotional disturbances may disappear as the result of psychotherapy. A mild sedative is often helpful, such as one of the bromide salts, from 0.6 to 1 Gm. (10 to 15 grains), dissolved in a suitable vehicle and taken three or four times a day. Phenobarbital, from 0.015 to 0.03 Gm. (one-fourth to one-half grain) in tablet form, serves the same purpose. Sedation is discontinued as improvement takes place.

One of the early signs of myocardial insufficiency is the occurrence of ventricular premature contractions. Taking digitalis usually causes the irregularity to disappear. This drug is best given by mouth, as the whole leaf, dispensed in the form of tablets, pills or capsules. One digitalis unit¹ (approximately 0.1 Gm., or 1½ grains) of a biologically standardized product (such as digitalis pulverata, U. S. P.) is administered three times a day for four days, twice a day for three days and then once a day for a week. The required daily dosage and total amount will vary with each patient; the scheme outlined serves only as a guide. Full digitalis action, as required in the presence of advanced congestive failure, is not necessary. The drug may be stopped when regular rhythm has been established. Sometimes a continued maintenance ration is necessary to prevent relapse (from 0.05 to 0.2 Gm., or three-fourths grain to 3 grains daily). It must be kept in mind not only that digitalis will abolish premature beats but that this arrhythmia is one of the early signs of poisoning by the foxglove.

In cases of coronary atherosclerosis in which there is no evidence of cardiac insufficiency, areas of local myocardial ischemia not infrequently appear to initiate this type of irregularity. Digitalis is the most useful drug in abolishing it and is given as described for the treatment of early congestive heart failure.

Should digitalis be poorly tolerated, as happens on rare occasions, squill may be substituted in the form of the product marketed under the name "urginin." This preparation, composed of equal parts of two water-insoluble glucosides (scillonin A and B), has an action on the heart like that of digitalis. One 0.5 mg. (½₁₀₀ grain) tablet is the approximate equivalent in therapeutic activity in man of 0.1 Gm. (1 digitalis unit) of digitalis leaf. Uarginin is frequently well taken by those in whom digitalis causes local digestive discomfort, but it possesses no other advantages.

Quinidine sulfate is another drug that is occasionally useful, but less so than digitalis. The dose is 0.2 Gm. (3 grains) three or four times a day, in capsule or tablet form. Phenobarbital, from 0.015 to 0.03 Gm. (one-fourth to one-half grain), may sometimes be given with quinidine to advantage. In my experience quinine is less effective than quinidine, and its efficacy is not enhanced by combining it with strychnine, as has been recommended.

AURICULAR FIBRILLATION

Auricular fibrillation is due to the establishment in the auricles of a circus movement, which travels at a varying but rapid rate over an irregular course, about the mouths of the great veins. The ventricular rate in an untreated case is usually fast. There are two ends to be achieved by drug therapy: first, to slow the rate of beating of the ventricles; second, under certain conditions which will be defined, to restore sinus rhythm.

Regardless of etiology, the ventricular rate, if rapid, must be retarded. This is accomplished by administering digitalis, which is effective in either the presence or the absence of congestive failure. Its action in slowing the ventricles is more pronounced in rheumatic and coronary heart disease than in hyperthyroidism, or in cases associated with toxemia due to bacterial poisons. Digitalis acts by depressing the conductivity of the junctional tissues and producing incomplete auriculo-

From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Medical Clinic of the Presbyterian Hospital.

1. U. S. P. XI (1936) digitalis is from 25 to 30 per cent stronger than the digitalis of the U. S. P. X (1926). The U. S. P. XI digitalis unit is also somewhat stronger than the Hatcher-Brody cat unit.

ventricular block. As a result, only part of the impulses from the auricles are permitted to reach the ventricles. The degree of block, and hence the ventricular rate, can be regulated by the amount of the drug given.

The total therapeutic dose of digitalis will vary according to the degree of cardiac insufficiency and the susceptibility of the individual. The amount necessary to induce a full effect in a person who has not previously taken digitalis is between 1 and 2 Gm. (15 and 30 grains), given in the course of two or three days. Usually 1 Gm. can safely be given in the first twenty-four hours in divided doses. In the second twenty-four hours 0.5 Gm. ($7\frac{1}{2}$ grains) may be administered. A suitable interval between doses is from four to six hours; but the rate of digitalization can be varied according to the urgency of the indications. Subsequent therapy will depend on the effect observed on ventricular rate, the ultimate aim being to lower this to a level ranging between seventy and eighty beats a minute, with the subject at rest.

In fibrillation of recent onset, sinus rhythm may be resumed after digitalis has been taken, owing to improvement in the function of the myocardium. If fibrillation persists, a daily maintenance ration should be continued. The patient with permanent auricular fibrillation must, as a rule, take digitalis for the rest of his life. The daily dose may be as little as 0.05 Gm. or as much as 0.3 Gm. The average is 0.1 Gm. Each case is the subject of experiment in this respect, with the ventricular rate, at rest, serving as guide.

After surgical operation or in the presence of nausea and vomiting, digitalis may be given by rectum, as the tincture or in a suppository. Absorption is good. The dosage is similar to that used by mouth. Intramuscular injections may be employed when oral or rectal routes are not available.

In rare cases an immediate slowing of rate seems imperative. Under these conditions crystalline strophanthin (ouabain), injected intravenously, is the preparation of choice, because its known chemical composition makes accurate dosage possible. An initial effect is apparent in from five to twenty minutes and a maximal effect in from fifteen to fifty minutes. At the first dose 0.5 mg. ($\frac{1}{20}$ grain) is injected; this is followed at intervals of one hour or more by 0.1 or 0.2 mg., up to a total dose of 1 mg. Treatment is then continued by giving a preparation of digitalis by mouth, by rectum or by intramuscular injection.

The toxic effects of digitalis are now well known. Nausea, vomiting, diarrhea and the occurrence of premature contractions are among the earlier evidences of poisoning. With larger doses, ventricular tachycardia may appear. As soon as any one of these is noted, the drug should be discontinued.

Restoration of normal rhythm can be brought about, in certain cases, by the use of quinidine sulfate. The number of patients suitable for receiving this drug is not large because of the dangers from its administration and the limitations in its effectiveness. Some persons experience tinnitus, nausea, vomiting or diarrhea as minor discomforts. More serious toxic effects are syncope, collapse, embolism, induction of cardiac insufficiency, ventricular tachycardia and, on rare occasions, sudden death. By careful selection of suitable cases the chance of success in altering the rhythm is increased and the possibility of grave accident is minimized.

Contraindications to the employment of quinidine are idiosyncrasy to cinchona derivatives, fibrillation of long standing, significant cardiac enlargement, mitral

stenosis, active carditis, congestive heart failure, previous occurrence of emboli to lungs or systemic arteries, partial or complete heart block, bundle branch block and hyperthyroidism. Favoring its use are a competent myocardium, fibrillation of recent onset, little or no cardiac enlargement, no structural valvular defect and fibrillation persisting after subtotal thyroidectomy for hyperthyroidism. It is clear that quinidine is a drug which is to be given to a small group of patients.

Resumption of normal rhythm does not greatly improve the clinical status of most patients with organic heart disease and fibrillation of long standing (longer than six months). There is always the possibility, and indeed the probability, that fibrillation will recur, with sudden onset of a rapid ventricular rate. Another period of rest and therapy is then required. On the other hand, if the functional capacity of the heart muscle is good and the ventricular rate is held at a proper level by continued digitalis dosage, a more stable condition is maintained. Though the auricles continue to fibrillate, the patient can pursue his prescribed activity with comfort and freedom from upsetting episodes.

Cardiac insufficiency, when present, should be treated by suitable measures before quinidine is given. The ventricular rate, if rapid, is controlled by digitalis. But before quinidine is started it is well to stop the administration of digitalis, because its action favors persistence of the circus movement. Quinidine therapy should be carried out with the patient in bed under careful observation, preferably with electrocardiographic control. It is not a procedure applicable to ambulatory patients.

Several plans for dosage have been suggested and found satisfactory. One that can be recommended is as follows: Individual doses are given by mouth, in the form of capsules or tablets, at intervals of two hours. First day, two doses of 0.2 Gm. (3 grains) each; these are to test for possible idiosyncrasy to the drug. If symptoms of cinchonism appear, treatment is abandoned. Occasionally normal rhythm follows administration of such small preliminary doses. Second day, three doses of 0.4 Gm. (6 grains) each. Third day, four doses of 0.4 Gm. each. Fourth and succeeding days, five doses of 0.4 Gm. each. In a few cases from six to eight doses in a day have succeeded where five have failed, but the larger amounts are not without added risk. The treatment may be continued for a week; but usually, if success is obtainable, from four to six days of this dosage suffices. If it should prove necessary to continue beyond this period, normal rhythm, though sometimes restored, rarely persists for long. Intravenous injection of quinidine is inadvisable; several fatalities have followed this procedure.

After resumption of normal rhythm it is desirable to continue with small doses of 0.2 Gm. three times a day for several weeks. These aid in preventing relapse. Such amounts, or even larger doses (0.4 Gm. three or four times a day) may be taken for weeks or months without harm or discomfort. A similar plan may be followed, often with good results, in cases of paroxysmal fibrillation, to prevent the occurrence of attacks. If, however, these recur at frequent intervals, fibrillation is allowed to persist, and the ventricular rate is controlled by digitalis.

AURICULAR FLUTTER

As in fibrillation, the mechanism at the basis of flutter is a circus wave in the auricles. In flutter, however, the circus wave follows a fixed path at a constant rate.

Its speed determines the rate of auricular contraction, which ranges in different cases from 200 to 400 a minute. Depending on the degree of auriculoventricular block, the rate of the ventricles is rapid or slow.

If the ventricular rate is fast, digitalis is indicated and is the drug of choice. It is given in the same manner as that outlined for fibrillation. Following full dosage, the rhythm is usually converted into fibrillation. When this occurs, and if the ventricular rate is slow, digitalis is stopped. After the lapse of several hours, normal rhythm may be resumed without further medication. If, in spite of apparent digitalis action, the mechanism of flutter persists, quinidine may be tried. The plan of dosage is the same as that given for fibrillation. But, if the foxglove has failed, quinidine is rarely effective. Should flutter be converted to fibrillation and the latter continue, quinidine may be expected to restore normal rhythm. Paroxysmal flutter is much less common than paroxysmal fibrillation. The prophylactic use of small doses of digitalis or quinidine may be tried if attacks are sufficiently frequent to cause discomfort.

Occasionally auricular flutter is resistant to all drug therapy and the disordered mechanism persists. If the ventricular rate is controlled by digitalis and the myocardium is competent, patients can carry on their customary activities without discomfort. In several reported cases normal rhythm has been resumed spontaneously, for no apparent reason, after flutter had been present continuously for months or even years.

PAROXYSMAL TACHYCARDIA

Paroxysmal tachycardia is observed frequently, though not invariably, when there are no anatomic lesions in the heart. It is due to a rapid succession of ectopic beats arising in auricles, junctional tissues or ventricles, occurring regularly at rates ranging from 150 to 200. The onset and offset are sudden, and the patient is usually aware of both. The duration of a paroxysm is from a few hours to a number of days; spontaneous cessation is the rule. Prolonged tachycardia may result in cardiac insufficiency, especially when there is impairment of the myocardium due to disease.

The effectiveness of any particular form of therapy cannot be foretold; each case appears to vary in its response. The attacks may be short and require no treatment by drugs. Simple mechanical procedures to terminate them should first be tried, such as carotid or ocular pressure, forced breathing, leaning forward in a chair with the head low or forced breathing with the glottis closed. If tachycardia persists and the patient is distressed, a triple bromide tablet, 1 Gm. (15 grains), may be taken every four hours for several doses. Sometimes morphine sulfate, one-fourth grain (0.015 Gm.), allays discomfort and appears to aid in stopping the attack. If recurrences are frequent morphine should not be used repeatedly, because of the danger of addiction. I have seen one such instance.

If these measures are ineffectual, acetyl-beta-methylcholine chloride (mecholy) may be injected subcutaneously in a dose of from 20 to 40 mg. (one-third to two-thirds grain). It acts by stimulating the vagus nerves. As a rule the attack ceases abruptly in from one to twelve minutes. The drug frequently causes unpleasant symptoms, among which are dyspnea, sweating, flushing and salivation; there may be vomiting and substernal pain. Some patients prefer the discomfort of the paroxysm to the distress caused by the remedy. Atropine sulfate 1.2 mg. (one-fiftieth grain), injected intravenously, will neutralize the effects of acetyl-beta-

methylcholine chloride almost at once and may be given if the reaction is stormy. Acetyl-beta-methylcholine chloride, though not a dangerous drug, should be used cautiously for patients with asthma and those suffering from conditions responding to epinephrine, which is a physiologic antagonist of the choline.

Syrup of ipecac, from 8 to 16 cc. (2 to 4 teaspoons), may be taken by mouth to induce nausea or vomiting. It produces reflex vagal stimulation and so can end a paroxysm. If the desired effect is not obtained after one hour, the dose may be repeated. The result is unpleasant but the procedure is simple and sometimes succeeds.

For prolonged attacks, especially if signs of cardiac insufficiency appear, digitalis should be given orally in full doses. It supports the failing heart and its use is often followed by cessation of the tachycardia. Injection of digitalis or strophanthin by vein is not without hazard, and the action is uncertain.

In some cases quinidine sulfate by mouth restores sinus rhythm. Doses of 0.4 Gm. (6 grains) are given every two hours until five or six have been taken. One or two doses may suffice. In tachycardia of ventricular origin, quinidine is particularly effective. When the arrhythmia follows myocardial infarction, large amounts are sometimes necessary and are well tolerated. As much as 0.8 Gm. (12 grains) may be given every two hours for five, six or more doses. After coronary occlusion it is desirable to end the tachycardia promptly in order to spare the damaged heart muscle from doing added work. The intravenous injection of quinidine has been tried and, on occasion, has been effective. It is not recommended because of the danger of inducing sudden cardiac standstill.

The use of drugs to prevent the recurrence of attacks may be tried, but the result is uncertain. Quinidine sulfate in doses of 0.2 Gm. (3 grains) three or four times a day, is the remedy most likely to act prophylactically and, if effective, may be continued indefinitely. In some cases digitalis in full amounts, followed by a daily maintenance ration, appears to be a better preventive. When the attacks are precipitated by emotional upsets, sedatives such as the bromides or phenobarbital raise the threshold for disturbing influences and so lessen the tendency for setting off the "trigger mechanism."

COMPLETE AURICULOVENTRICULAR BLOCK

Like other arrhythmias, complete auriculoventricular dissociation may be transient or permanent. It is caused by diseases or drugs which prevent conduction through the junctional tissues. Lesions due to rheumatic fever, syphilis, coronary atherosclerosis or the toxin of diphtheria may regress with proper therapy, and normal conduction is resumed. The effect of digitalis wears off if its administration is stopped. Structural damage or functional impairment sometimes persists and heart block becomes permanently established.

Uncomplicated permanent block does not require treatment by drugs. If the heart muscle is functionally adequate, the circulation is not seriously handicapped by the slow ventricular rate (idioventricular rhythm). If congestive failure appears, it is treated in the usual manner, including the use of digitalis. When auriculoventricular block is complete, digitalis may even accelerate slightly the rate of beating of the ventricles. Quinidine is apt to exert a harmful action in the presence of heart block and should not be employed, even though the auricles are fibrillating.

Occasionally, long periods of ventricular standstill or paroxysms of ventricular fibrillation result in cerebral anoxemia and this, in turn, causes dizziness, syncope or convulsive seizures (Adams-Stokes syndrome). It is necessary to know which mechanism is responsible for the attacks in order to carry out appropriate therapy. If the attacks are associated with ventricular asystole and are frequent, epinephrine is the best preventive. It is given in doses of from 0.5 to 1 cc. (8 to 15 minims) of the 1:1,000 solution by subcutaneous or intramuscular injection. The dose may be repeated every two hours if necessary and continued for a day or more. On those rare occasions when ventricular standstill is markedly prolonged, intracardiac injection of epinephrine may save life. Epinephrine should not be used when the attacks are due to ventricular fibrillation, since its action favors the continuation of this mechanism.

If ventricular standstill tends to recur, ephedrine sulfate is sometimes partially or wholly effective as a prophylactic. Like epinephrine, it increases the irritability of the ventricular muscle. Ephedrine is given by mouth in doses of 30 mg. (one-half grain) three or four times a day and may be continued, if indicated, for weeks or months. Barium chloride and atropine sulfate have also been tried as preventives but are, in the experience of most observers, less effective.

NUTRITIONAL DISEASES IN THE UNITED STATES

• CLINICAL LECTURE AT NEW YORK SESSION

W. H. SEBRELL, M.D.

Surgeon, United States Public Health Service

WASHINGTON, D. C.

During the past few years, attention has been increasingly focused on the problem of the recognition and treatment of nutritional diseases in this country. Ten years ago it was thought that we needed to concern ourselves only with rickets, pellagra and a little scurvy. Today it is recognized that all of the known nutritional diseases probably exist to some extent in the United States. Those that appear to be of most importance are anemia, due to iron or cobalt deficiency; nutritional edema, due to protein deficiency; hyperkeratosis and night blindness, due to vitamin A deficiency; beriberi and peripheral neuritis, due to thiamine (vitamin B₁) deficiency, frequently secondary to such conditions as alcoholism, pregnancy and diabetes; lip lesions, seborrhea and keratitis, due to riboflavin deficiency; pellagra or encephalopathy, due to nicotinic acid deficiency; swollen bleeding gums, skin and subperiosteal hemorrhages, due to ascorbic acid deficiency; rickets and osteomalacia, due to vitamin D deficiency; hemorrhagic disease of the newborn, due to vitamin K (phthiocol) deficiency; tetany, due to hypocalcemia, and probably many other at present less well identified conditions with a nutritional background. It is very difficult to estimate the prevalence of these diseases, since they usually do not figure prominently in physicians' reports, and the number of deaths reported is small.

Just as a matter of interest, the reported deaths from a few of them as given by the United States Census Bureau for the period 1934-1938 are given in table 1. This table reveals some interesting facts. First, the total number of deaths from all these conditions is relatively insignificant except for pellagra. This fact has led the United States Public Health Service to put great emphasis on the prevention of this disease. The 1939 figures are not yet available from the Census Bureau, but it is to be expected that there were fewer deaths in 1939 because of the widespread use of nicotinic acid in treating this disease.

Another interesting fact to be seen in this table is the decrease in the number of deaths between 1934 and 1938 in all these diseases with the exception of beriberi. The number of deaths from beriberi in 1938 is about eight times that of 1934. Is this a real increase or is it due to better diagnosis and increased attention to this condition? There is no information available which will enable us to answer this question, although one is inclined to believe that at least part of the increase is due to better diagnosis. On the basis of the small total number of deaths per annum given in this table, in comparison with our approximately 30,000 annual deaths from diabetes, the first impression is that these diseases are relatively insignificant as a medical problem. However, it must be remembered that these are not killing diseases and the number of deaths affords little information with regard to the amount of sickness and disability. For example, iron deficiency anemia does not appear at all, yet Abbott and Ahmann¹ found that 50 per cent of 883 Florida rural school children were anemic, with hemoglobin values of 70 per cent (9.64 Gm.) or less; and some children with hemoglobin values even as low as 25 per cent were attending school. There was rapid regeneration of hemoglobin following the administration of iron and ammonium citrates to 200 children.

A few years ago it was estimated that the death rate from endemic pellagra did not exceed about 3 per cent on the basis of survey data collected by Goldberger and his associates² in 1917. This figure is probably too high today because of the number of lives now being saved by improved methods of treatment. On this basis, however, the 3,200 deaths from pellagra represent at least 100,000 cases—a figure which, in all probability, is an underestimate when the cases of nicotinic acid deficiency without cutaneous lesions as manifested by psychosis and encephalopathy are taken into consideration. There is much additional indirect information which indicates that the nutritional diseases are taking an enormous toll in illness and disability in this country. For example, Nelson³ of the United States Food and Drug Administration estimates that in 1938 the people of the United States spent more than \$100,000,000 for vitamin preparations manufactured or sold through pharmaceutical channels, or approximately \$1 for every man, woman and child in the United States. In this connection the figures on the value of vitamin products manufactured in the United States in 1937, as obtained by the United States Department of Commerce⁴ are given in table 2.

4. Census of Manufacturers, 1937: Drugs and Medicines, United States Department of Commerce, Bureau of the Census, Feb. 3, 1939.

From the National Institute of Health.
Read in the Medical Division of the General Scientific Meetings at the Ninety-First Annual Session of the American Medical Association, New York, June 11, 1940.

The value at the factory totals \$26,898,500, which with the usual retail mark-up of 100 per cent represents \$53,797,000 spent by the public for these preparations. It is of interest to note that the greatest expenditure, about \$21,000,000, was by the general public on vitamin products which did not comply either with the United States Pharmacopeia or with the National Formulary. This figure for 1935 was only about \$4,700,000. In other words, the business of self medication with vitamin preparations increased about fivefold in two years. Does this indicate a widespread prevalence of mild disability due to vitamin deficiencies or was this money

largely wasted? It probably is an indication of the success of advertising campaigns rather than sales due to real needs, since people with money enough to purchase such preparations do not constitute the large group of our population most likely to be getting a deficient diet. However, because of dietary fads and complicating diseases, undoubtedly some of this expenditure was worth while. Of more significance to us is the \$13,114,000, representing about \$26,000,000, expended on vitamin prescriptions prescribed by physicians. A figure of this magnitude must mean that physicians are becoming increasingly aware of the value of these preparations in treatment, and conversely that vitamin deficiency symptoms are widely prevalent. In addition it must be remembered that these figures, which are the latest available, are for 1937, before either nicotinic acid or riboflavin had come into wide medical use, and before much of the importance of these substances was recognized. Because of the money spent for these preparations the figure for 1939 probably will be much higher.

There is another line of evidence which indicates that the deficiency diseases may be very common and of great medical importance in this country. This evidence is based on food consumption studies.

While we have been improving our diets in some respects during the past century, they have been becoming more deficient in others. Stiebeling and Coons⁵ show that during the past fifty years there has been a decline in the consumption of grain products and meats and an increase in the consumption of milk, green leafy vegetables, tomatoes and citrus fruits. Jolliffe⁶ has pointed out that changes in wheat milling practice and decrease in grain consumption, which has been compensated by increased sugar consumption, has materially reduced the vitamin B₁ content of the American dietary during the past century. In addition to changes in dietary habits which have affected the nutritive value of the diets of most of us, there are two other important factors to be considered. The first of these is income. Under present conditions many people in this

country cannot afford to purchase an adequate diet. Stiebeling and Phipard⁷ have shown that city families with food expenditures of \$1.25 a person a week have restricted diets, while with more money to spend for food the nutritive value of the diets improved. Hambidge⁸ estimates that those who cannot now afford an economical fair diet are largely among those with incomes of less than \$750 a year, a group which he estimates includes 32 per cent of all the families and single individuals in the United States; or, to put it another way, three out of every ten city and village families do not have enough money to spend for food to get a good, completely adequate diet.

The situation does not appear to be any better with regard to farm families, in spite of the fact that they usually produce part of their own food supply. Stiebeling and Coons⁵ state that farm families with money and nonmoney incomes under \$1,000 a year scarcely included enough fruits and vegetables in their diets even in the summer months, and on the basis of figures from the National Resources Committee more than 60 per cent of the families of nonrelief farm operators in the Southeast and more than 40 per cent in the Northeast in 1935-1936 had total incomes, both money and nonmoney, of less than \$1,000. They conclude, therefore, that a large proportion of farm family diets are poorly supplied with fruits and vegetables.

To this very large group of our population which apparently subsists on an inadequate diet because of low income must be added another group of undetermined size which obtains an inadequate diet because of ignorance, improper dieting, food faddism or carelessness in spending their food money, although their income is adequate to furnish a proper diet if the money were spent wisely. Without attempting to put any specific figure on the number of people affected, such data indicate that in all probability the nutritional diseases constitute our greatest medical and public health problem, not from the point of view of deaths, but from the point of view of disability and economic loss, a fact

about which we have been misled by the very low death rate and inadequate diagnosis.

People who have studied the subject, therefore, are not surprised at the volume of the current sales of vitamin products, the increasingly large number of reports on the value of various vitamins for a wide variety of conditions or the increasing use of these preparations by practitioners. It is probable that the majority of all the patients coming to the general practitioner today are given vitamin or mineral preparations in some form in the course of their treatment with apparent benefit. Because of the lack of specific diag-

nostic methods and the vagueness and diversity of the symptoms, many physicians are likely to be careless in making an accurate diagnosis and in prescribing the proper specific therapy. It is essential that accurate diagnosis be made if treatment of the severer symptoms is to be adequate. Since as a rule large doses of the specific vitamin are necessary immediately, and frequently by parenteral injections, it may not be enough to try to solve the problem by giving some proprietary preparation reputed to contain all of the vitamins needed by man, beast or plant, since such preparations rarely have enough of any one substance to be of much therapeutic value. However, it is important also to recognize that frequently the symptoms of more than one nutritional disease are simultaneously present. This is to be expected because deficient diets are not likely to be deficient in only one factor; and, if the diet is deficient enough to produce symptoms of one deficiency, it is not unusual to find symptoms of another deficiency; or, if the diet is not improved along with specific treatment, symptoms of another deficiency may develop while the patient is under treatment. This is especially true of the members of the vitamin B complex, since these factors are usually found in varying amounts in the same foods. These deficiencies constitute a large part of our nutritional problem, the extent of which is not yet entirely clear because of the complexity of this group of substances. To date five members of this complex have been isolated, chemically identified and synthetically prepared. These are thiamine hydrochloride, nicotinic acid, riboflavin, pyridoxin (formerly called B₆) and pantothenic acid. In addition to these there are an uncertain number of others which are as yet unidentified, the importance of which for man has not been determined. When it is remembered that the value of nicotinic acid was discovered only late in 1937, the phenomenally rapid progress that has been made in this field can be understood. At that time only pellagra and beriberi were being recognized. The next syndrome to be identified was that of human riboflavin deficiency, which was recognized by Sebrell and Butler⁹ as a separate entity late in 1938 and we are still learning things about it. The symptoms of this deficiency appear to be identical with those previously described as pellagra sine pellagra, but identification became possible only after both nicotinic acid and riboflavin were made available. The typical lesion is a macerated linear fissure in each angle of the mouth, designated by earlier writers as angular stomatitis. Accompanying this the lips become sealy, appear "chapped" and have a shiny reddened, denuded appearance. For this reason it is preferable to call the entire lip lesion a cheilosis. Along with the lip lesion there is a mild, greasy, seborrheic dermatitis on a slightly erythematous base at the nasolabial folds and in some cases at the inner or outer canthi. In many cases there is also a crusty, superficially eroded lesion just inside the nares and there may be a vertical fissure at the mucocutaneous junction. Occasionally the seborrheic dermatitis is also seen about the ears or on the face and may involve other parts of the body. In addition the tongue becomes a magenta color, which can be distinguished from the bright red tongue of pellagra. These lesions may persist for months unless a correct diagnosis is made and riboflavin therapy started. Within the past few months it has been recognized that a keratitis also occurred in many

cases of this kind and that the keratitis would respond rapidly to riboflavin treatment.

Eye lesions in experimental animals with riboflavin deficiency have been noted by many observers. Goldberger and Lillie¹⁰ saw "ophthalmia" in rats on diets which are now recognized to be deficient in riboflavin. Day and his associates¹¹ have made several reports on the relationship between cataracts and riboflavin deficiency in rats, and Bourne and Pyke¹² saw cataracts and keratitis in rats on riboflavin deficient diets. Bessey and Wollbach¹³ and Eckardt and Johnson¹⁴ have reported a high incidence of keratitis in rats on riboflavin deficient diets, and Bessey and Wollbach¹³ found vascularization of the cornea to be the earliest and most constant manifestation of riboflavin deficiency in the rat. O'Brien¹⁵ also noted lesions of the iris and mydriasis in his rats, and El-Sadr¹⁶ noted corneal infiltration (pannus), corneal ulcers and cataracts in rats on riboflavin deficiency and found that the corneal opacity disappeared within a few hours after a single dose of 50 micrograms of riboflavin.

In addition to this evidence from animal experimentation there are many references to eye lesions associated with deficient diets in human beings which may have been related to riboflavin deficiency. The very early writers on pellagra, such as Soler¹⁷ in 1791 and Rampoldi¹⁸ in 1885, refer to such eye symptoms as inflammation of the cornea, corneal ulcers and opacities, and among the early writers on pellagra in this country Clark¹⁹ in 1909 reported pain in the eyes, conjunctivitis, failing vision and iritis, and Whaley²⁰ saw photophobia, mydriasis and superficial inflammation of the cornea among other eye lesions in pellagrins. It seems not unlikely now that, in view of the close association frequently seen between riboflavin deficiency and pellagra, many of these lesions may have been due to riboflavin deficiency. Last year Spies, Vilter and Ashe²¹ again called attention to such lesions and stated that more than 70 per cent of the patients in their nutrition clinic with frequent recurrences of pellagra, beriberi or riboflavin deficiency also have visual disturbances, some of which are characteristic of vitamin A deficiency. They noted bulbar conjunctivitis, lacerimation, burning of the eyes and failing vision which in some instances responded to riboflavin therapy, although they saw similar lesions respond to large doses of carotene. Ashe²² noted a history of "visual disturbances" in patients with other symptoms of riboflavin deficiency, which disappeared in from four to six days following the administration of riboflavin. Pock-Steen²³ has reported that symptoms of photophobia, dimness of vision, mydriasis and keratitis in 109 patients with sprue were cured by riboflavin. Therefore, without attempting to give an exhaustive review of the literature it may be stated that a variety of eye symptoms have been associated with deficient diets for a long time. Within the past few months much additional light has been thrown on the subject by the contributions of Kruse, Sydenstricker, Sebrell and Cleckley.²⁴ Forty-seven patients with riboflavin deficiency showed slit lamp evidence of a vascularizing keratitis, accompanied by such symptoms as photophobia, dimness of vision, circumcorneal injection and a burning sensation of the eyeball. Gross injection of the vessels of the fornix and sclera without evidence of infection gave the picture of conjunctivitis; some showed corneal opacities, mydriasis and iritis. There was spectacular improvement in these symptoms following the administration of from 5 to 15 mg. of riboflavin daily. At the same time repeated slit lamp examinations showed rapid resolution of the keratitis and emptying of the vessels in the cornea. It was then demonstrated that the vessels on the cornea would refill with blood following withdrawal of riboflavin, and again could be made to collapse by giving riboflavin. This discovery that a keratitis is the eye lesion in man associated with riboflavin deficiency is in accord with the lesions demonstrated by Bessey and Wolbach on the rat and is supported by the more recent observations of Johnson and Eckardt²⁵ that riboflavin is of value in rosacea keratitis.

It therefore appears that at least some of the many cases of keratitis in this country of vague or unexplained etiology, even without lip or tongue lesions, are due to riboflavin deficiency. This work indicates that unrecognized riboflavin deficiency is perhaps very widespread in this country and is another indication of the probable extent of nutritional diseases.

Other recent work on the therapeutic application of vitamins to other conditions such as the use of vitamin E (alpha-tocopherol) in the treatment of muscular dystrophy or amyotrophic lateral sclerosis reported by Wechsler,²⁶ Bicknell²⁷ and Stone²⁸ and the use of vitamin K in hemorrhagic diseases of the newborn by Waddell and Guerry²⁹ are continually widening the field of clinical application of these substances. With constantly improving methods of early diagnosis of deficiency states revealing deficiencies hitherto unexpected by the clinician, and with intensive studies of the appli-

cation of the newly available pure vitamin preparations to conditions of questionable etiology rapidly revealing new therapeutic uses, physicians are becoming increasingly aware of the magnitude of the field, and of the many problems yet to be solved. Here is, indeed, one of the most fruitful fields of medical investigation, and one which is advancing so rapidly that it requires constant reading to keep up, and I want to close with the statement that the prevention and proper treatment of the nutritional diseases constitute one of the greatest medical problems in this country today.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

PROGRESS REPORT OF THE CONSULTANTS ON AUDIOMETERS AND HEARING AIDS OF THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION

Significant progress and advancement in the science of acoustics have led to a definite improvement in all the industrial and professional phases of hearing aids and audiometers. For example, in the advent of the thermionic tube a new method of measuring the acuity and range of human hearing is placed at the disposal of the medical profession. This method provides a means whereby controlled tones, with respect to intensity and pitch, can be applied to the human ear and a permanent record made of the hearing. Far more accurate is this method than the ones it superseded where tuning forks, acumeters, whistles or watches were used.

Even though much scientific progress has been made, many difficult problems face those who endeavor to aid the deafened. In instances in which acquiring a hearing aid may help, both the otologist who recommends wearing an instrument and the manufacturer who sells it must seek to overcome a peculiar type of resistance in the deaf person. Although hearing aids become less noticeable as they diminish in size they still are quite visible, and in some instances there seems to be retained some vestige of the sardonic situations associated with the old fashioned ear trumpet. A sensitive person sometimes refuses to wear the device or, if he does, he does so reluctantly and as a last resort. False pride, therefore, hinders some in becoming adapted to the use of a good hearing aid.

Some years ago, much the same type of resistance was met by the ophthalmologist who recommended the wearing of eye glasses. This resistance has not entirely vanished, but today glasses usually are worn readily by those requiring them. The problems of the person who should wear a hearing aid and of those who must wear glasses are not altogether parallel; however, the common acceptance and wearing of glasses would seem to indicate that, in the future, hearing aids will become more commonly accepted and generally worn. Before the instruments reach a desired perfection and do gain this acceptance, many problems confronting the otologist and the manufacturer of audiometric equipment must be met and solved.

Although audiometers of reliable construction had been marketed for many years, no standards for the instruments had been fixed or generally accepted, and although the Council on Physical Therapy had considered hearing aids for inclusion on its list of accepted devices, no great progress in the art of helping the deafened had been made. In 1935 it was observed by the late Dr. Austin A. Hayden, Secretary of the Board of Trustees of the American Medical Association, that an efficient procedure might be for the Council to appoint a group of consultants, having special training and experience in the field, to assist in setting up minimum requirements for acceptance of audiometers and hearing aids and to help in the consideration of them as well as the conservation of hearing. His recommenda-

tion to the Board of Trustees that such a group be appointed was supported by Drs. Thomas S. Cullen, Ralph A. Fenton and the late Charles Wright, members of the Board of Trustees who had a special and personal interest in the problem. In 1936 the Council was authorized to appoint a group of consultants for this purpose.

Appointed as consultants on Dr. Hayden's recommendation were Drs. George M. Coates, Lec W. Dean, Edmund P. Fowler, Isaac H. Jones, Douglas Macfarlan, Horace Newhart, Burt R. Shurly and William P. Wherry. C. C. Bunch, Ph.D., took over the work of Dr. Dean at the latter's request, and Dr. C. Stewart Nash was appointed as a consultant in July 1939. At the first meeting Dr. Newhart moved that Dr. Hayden be appointed chairman and he was duly elected. Paul Sabine, Ph.D., of the Riverbank Laboratories, and W. C. Beasley, Ph.D., of the United States Public Health Service, have given generous assistance to the Council.

In order that the special problems facing those interested in prescribing and making hearing aids available to the deafened might be more clearly understood and effectively handled, it was considered necessary to pursue a course especially suited to dealing with the problems. What proved to be a very effective method of promoting mutual understanding between otologists and hearing aid manufacturers was a series of joint meetings of representatives of each group. Hence, according to the minutes of the Board of Trustees, by motion of Dr. Hayden, seconded by Dr. Wright, funds were made available for holding the first of the conferences, where the consultants met with the manufacturers of audiometers and hearing aids. Since then the Board has continued its cooperation with the Council and consultants in authorizing additional appropriations to carry out this special program.

A conference of this nature is not amenable to the procedure of the Council on Physical Therapy because of time limitations when the Council holds its meetings. However, the Council felt that such a meeting would be of great value for the consultants in evaluating all the phases of the problem. Personal contacts of this kind between the consultants and representatives of the manufacturers have proved very useful; several consultants and the Secretary of the Council have also made inspection visits to plants where the instruments are manufactured. In all, three meetings have been held with most creditable results.

The first of the meetings, held at the Palmer House in Chicago, Aug. 8, 1937, provided an opportunity for each manufacturer of audiometers to acquaint the consultants with his unit through an actual demonstration of the apparatus. The advantages and limitations of each unit, and the extent to which it met the tentative requirements, were discussed. The great value of this meeting lay in the fact that it made it possible for the consultants to obtain better insight into the problems confronting the manufacturers of the instruments and it revealed to the manufacturers the difficulties otologists encountered in testing hearing and using the information in clinical practice.

The Council and the consultants had been of assistance to the American Standards Association subcommittee when that group formulated its Tentative Minimum Specifications for Audiometers for General Diagnostic Purposes. These specifications provided an excellent groundwork for the compilation of the Council's minimum requirements. However, a conference between the consultants and the representatives of audiometer and hearing aid manufacturers and voluminous correspondence were required before the adoption and publication of the Council's Tentative Minimum Requirements for Acceptable Audiometers. The publication date was Nov. 27, 1937.

The second joint meeting with the consultants and the manufacturers was also held at the Palmer House in Chicago; it took place Aug. 20, 1938. The Tentative Minimum Requirements for Acceptable Audiometers were considered further. Specifications for acceptable hearing aids, and the practicability of using the audiogram in fitting them, were also discussed. The claims made in advertising and the promotion of hearing aids were also considered. Both the consultants and the manufacturers were afforded a clearer conception of the problems of each by this discussion.

At the third joint meeting with the consultants and representatives of hearing aid manufacturers, held May 5, 1940, the

Minimum Requirements for Acceptable Audiometers were reviewed and the Tentative Minimum Requirements for Acceptable Electric Hearing Aids were given consideration. Several minor changes were made in each. Advertising claims advanced by the manufacturers for their instruments were discussed. Trial periods for prospective hearing aid purchasers were given consideration.

By far the greatest volume of the work and the majority of the deliberations have been carried on by correspondence. From time to time, usually once a month, communications or confidential bulletins are sent to the consultants from the A. M. A. headquarters in Chicago. Embodied in these mimeographed communications are reports, discussions and votes on the matter before the consultants. The questions are arranged so that ample space is given for discussion, criticism and voting. Questions are worded so that they recommend to the Council certain actions. The Council then acts on these recommendations, either accepting or not accepting them. Since the appointment of the consultants three years ago thirty-four communications, or about 600 pages of single spaced copy, have been sent to each of the members. An enormous quantity of advertising material has also been presented to them for review and criticism.

On Feb. 25, 1939, the Minimum Requirements for Acceptable Audiometers were published. Three audiometers have been accepted: the Maico Audiometer D-5, the Western Electric Audiometer 6B and the Jones-Knudson Audiometer, which is no longer on the market because of excessive cost of production. Other audiometers are before the Council and are still undergoing consideration. More recently the Council has considered the possibility of compiling minimum requirements for acceptable audiometers used for group screening tests. Two screening audiometers, a phonograph type and an oscillator type, have been submitted to the Council. For the first time in history real standards for audiometers to test hearing are available.

Although the Council had considered hearing aids prior to the appointment of the consultants in 1936, one hearing aid having been placed on the list of accepted devices in 1935, after the consultants became active much greater progress was made. There are now eleven hearing aids on the Council's list of accepted devices; seven are of the carbon granule type, two of the vacuum tube and two of the semiportable type. The accepted hearing aids are the Acousticon Hearing Aid, Coronation Acousticon Hearing Aid, Aurex Hearing Aid (semiportable), Radioear, Radioear De Luxe Type B-20, Maicophone Hearing Aid (vacuum tube), Ravox Hearing Aid (semiportable), Sonotone Hearing Aid, Telex Hearing Aid (vacuum tube), Western Electric Audiphone and Western Electric Audiphone, Ortho-Technic Model. Six hearing aids of the vacuum tube type are now undergoing consideration.

It is the opinion of the consultants, as expressed by Dr. Nash, that hearing aids should be fitted by otologists after a complete otologic examination including the inspection of aural polyps and the tympanic cavities for carcinoma or tumor, and audiometric test, tuning fork, voice and whisper test. The physician is in a better position to analyze the wants of a deafened patient than a technician or salesman. He will know whether lip reading instruction, a surgical operation or the application of a hearing aid is the correct way to solve the patient's problem. When a hearing aid is prescribed or fitted, Dr. Macfarlan points out that the otologist is better trained to test the efficiency of the aid by voice tests using words, syllables and meaningless phrases. However, the consultants feel that this is not the time to lay down any hard and fast rules to the effect that no aid should be sold without an otologic evaluation and physician's prescription.

Requests from insurance companies, courts of law, compensation boards and other interested groups have been brought to the attention of the consultants concerning the need of standardized tests for determining hearing loss and a method for estimating hearing loss in terms of percentage. At the annual session of the American Medical Association in St. Louis in 1939 the House of Delegates approved the program outlined by the Council to meet requests. This problem is now being considered by the Council and consultants.

When one special field of medicine comes to another with a controversial question, as pointed out by Dr. Wherry, each side

is aware of the difficulties involved in formulating a clearcut, definite answer, and the profession accepts a tentative answer which may be subject to revision. However, when industry comes to medicine with a question on a controversial subject, industry will be satisfied with nothing but a definite answer. As the question of ear impairment and percentage loss concerns industry through the compensation boards, courts of law and insurance companies, the answer given by the Council and consultants to this problem of the standardization of tests for hearing loss and the estimation of loss in terms of percentage must be clearcut and definite. As this is a highly controversial question, involving the combination of many variables that must be reduced to a common denominator, ample deliberation must be given to it before a final answer is made.

The Section on Ophthalmology of the American Medical Association has developed a method for estimating the visual acuity in terms of percentage; this method has been adopted by the House of Delegates. Many states have officially adopted it as the method of estimating visual loss. Industrial surgeons practicing orthopedic surgery have made significant advances in the estimation of percentage loss of movements caused by damage to extremities. The consultants and the Council are doing the same with hearing impairment.

A special committee of the consultants, comprised of Drs. Bunch, Hayden, Nash, Newhart, Sabine and Wherry, has been formed to deliberate on this question. Two methods for estimating the loss of hearing in terms of percentage are now being considered by the committee. One method was proposed by Dr. Bunch and the other by Dr. Fowler. Although they have been carefully considered for several months, a final decision has not yet been reached and it is the opinion of the committee that the acceptable method will involve some of the points of each of the proposed methods. More study will be required before the consultants and the Council can adopt a recommendation for estimating the loss of hearing in terms of percentage.

The consultants have given consideration to the problem of developing acceptable screening audiometers for use in schools, industrial plants and other institutions. The great value in the periodic testing of hearing of public school children in the prevention of deafness of any scale has often been pointed out by Dr. Newhart. Dr. Jones has written about the audiometer and its place in the educational field especially in the public schools. Dr. Shurly has demonstrated how the family physician may be consulted in connection with the information obtained from screening tests made in the public schools at Detroit. Although the consultants are giving consideration to the drawing up of minimum requirements for acceptable screening type audiometers, the data now available are not definite enough on which to build.

Part of the activities of the consultants have been devoted to education such as making available significant information on the clinical use of the audiometers, on how to take an audiogram and on the construction of the instrument. Thus the Secretary of the Council has presented exhibits at annual sessions of the American Medical Association and at meetings of the American Academy of Ophthalmology and Oto-Laryngology. These exhibits have been designed purposely to explain by means of demonstrational apparatus the makeup of physical characteristics of audiometers and hearing aids.

What is more important in education is instruction regarding the prevention of deafness. The program advanced several years ago by Dr. Coates on the prevention of deafness among industrial workers is still as sound today as it was then. Many of the consultants have given courses and exhibits at the annual meetings of the American Academy of Ophthalmology and Oto-Laryngology and read papers before the American Otological Society, the American Laryngological, Rhinological and Otological Society, Inc., and the Section on Laryngology, Otology and Rhinology of the American Medical Association.

The work of the Council and its consultants has been recognized by the American Society for the Hard of Hearing in that this organization has voted to place for publication in *Hearing News* after January 1941 only hearing aids accepted by the Council.

The consultants and the Council have not been without criticism. An apparent variation on different clinical audiometers

due to calibration has been noted by several observers. This variation arises in the amount of energy required for the threshold of hearing and also by the fact that the energy required for a threshold has not been fixed definitely by any authoritative body. Hence the consultants supported by the representatives of manufacturers will request the National Bureau of Standards to establish a standard threshold level as soon as possible.

It has been pointed out by Dr. Willis C. Beasley in connection with the work of the United States Public Health Service national health survey that sufficient information should be available to fix the standard for the threshold of hearing. Dr. Bunch has duplicated these results independently. It is believed that, together with U. S. Public Health Service data and the data collected at the Bell Telephone Laboratories' exhibit at the New York World's Fair, there are sufficient data to peg the threshold. It is relevant to add that the audiometers on the accepted list are calibrated to a threshold which will not be far from the ultimate accepted one. Various agencies have been working together for some time and thus agreement in opinion will probably not be difficult to achieve.

The Council has been questioned concerning the delay in the publication of acceptance reports of audiometers. One of the chief reasons for the delay was that the manufacturers of audiometers were apparently unable to meet the requirements which they themselves assisted in setting up and agreed as being just and reasonable. Another obstacle was the controversy over requirements with respect to purity of tone and maximum of intensity.

An explanation as to the delay in the adoption and publication of the requirements for acceptable electrical hearing aids also appears to be indicated, as there have been many requests for these requirements. Much advancement and many changes in the manufacturing phase are constantly occurring, and, in the opinion of the Council and the consultants, to set up restricting and unadaptable requirements would be a greater detriment to progress than not to set up any requirements at all. Tentative Minimum Requirements for Acceptable Hearing Aids were published in *THE JOURNAL*, May 11, 1940, and they are expected to go into effect in January 1941. These requirements are not to be interpreted as standards.

The procedure of the Council on Physical Therapy in the consideration of an audiometer or hearing aid is as follows: The Council on Physical Therapy is a standing committee of the Board of Trustees and its duties are to consider apparatus offered to the medical profession for diagnostic or therapeutic purposes, to study any methods of therapy involving physical agents (chemical agents excluded) and to assist in making such information available to the profession.

The members of the Council on Physical Therapy, as well as the consultants on audiometers and hearing aids, serve without remuneration. The Council members give consideration to and vote on questions submitted to them in the Council's confidential bulletin.

The booklet "Official Rules of the Council on Physical Therapy" is sent to the manufacturer of an audiometer or of a hearing aid who desires the Council's consideration of his instrument. The firm is asked to comply with the requirements given on the last two pages of the booklet and to submit a report from a qualified laboratory relative to the performance of the instrument, being guided by the Minimum Requirements for Acceptable Audiometers or by the Minimum Requirements for Acceptable Hearing Aids as the case may be.

The evidence submitted by the manufacturer is sent to an independent and impartial laboratory acceptable to the Council, where it is checked. If confirmed, a report is prepared recommending acceptance. If, however, the evidence submitted by the firm is not confirmed, a report of rejection is prepared and after adoption by the consultants and the Council it is sent to the manufacturer for his information prior to publication.

The final decisions of the Council concerning the acceptability or nonacceptability of audiometers and hearing aids along with other actions of the Council are published in *THE JOURNAL* from time to time under the Council's proceedings. The Council also edits a booklet entitled "Apparatus Accepted" in which audiometers and hearing aids are listed along with other apparatus having been accepted and placed on the list of accepted devices.

CONCLUSION

The Council on Physical Therapy and the Consultants on Audiometers and Hearing Aids have made the following advancements in the consideration of audiometers and hearing aids and the conservation of hearing:

1. Minimum requirements for acceptable audiometers have been formulated and adopted. The requirements have received universal acceptance on the part of otologists and manufacturers.

2. Three audiometers for diagnostic use have been investigated and accepted.

3. Requirements for acceptable hearing aids have been formulated and adopted.

4. Hearing aids have been investigated and accepted or rejected and this information has been made available to the profession and the public.

5. A survey of methods for determining the percentage of disability due to deafness has been started. The House of Delegates at the St. Louis session endorsed the work accomplished and objectives aimed at.

6. Information on devices used for treatment of hearing loss has been made available (e. g., stimulation of hearing by sound).

7. Advertising of acceptable hearing aids and audiometers has been reviewed, considered and criticized and much undesirable copy has been eliminated.

8. The Council has assured high standards of construction, workmanship and material.

Finally, the Council desires to express its appreciation to the Consultants on Audiometers and Hearing Aids for the valuable assistance that has been rendered by them for the past two years, and also to the several general and special medical societies for their cooperation.

SEARS S-4 SUNLAMP ACCEPTABLE

Manufacturer: Northern Electric Company, 5224 North Kedzie Avenue, Chicago.

Distributor: Sears, Roebuck and Company, Chicago.

The Sears S-4 Sunlamp produces ultraviolet radiation and consists of a standard mazda S-4 type bulb together with a standard reflector following the curvature and reflection specifications. The bulb is mounted in a socket permanently fixed in a socket housing which also holds the reflector, so that at all times the bulb will be at the proper location with reference to the reflector. The complete assembly of the bulb, reflector and socket are fixed to an adjustable standard mounted in a cast iron base which encloses the transformer.

The type S-4 mazda sunlamp consists of an electric arc discharge through mercury vapor between activated metal electrodes sealed in a small quartz capillary tube which, in turn, is enclosed in a bulb of special glass that is opaque to ultraviolet radiation of short wavelengths.

The radiation passing through the quartz capillary tube is essentially that of the so-called "hot quartz" mercury arc. However, by inclosing the quartz lamp in a bulb of glass of a composition and thickness to absorb completely the intense emission lines of wavelengths shorter than about 2,800 angstrom units, there remains a series of strong emission lines at 2,894, 2,967, 3,024 and 3,132 angstrom units (and longer wavelengths) favorably situated in the spectral band of ultraviolet in sunlight recognized as having a specific therapeutic effect, especially in curing rickets.

Operation: The S-4 lamp is operated on the ordinary (115 volts) house lighting (A. C.) circuit, but it requires an intermediary, especially designed, transformer to maintain the proper voltage and operating temperature. The approximate power used is 100 watts. In the lamps tested, on 115 volts input, the current through the lamp ranged from 2.1 to 2.3 amperes.

Radiation Measurements: In order to determine whether the type S-4 lamp complies with the Council's requirements of acceptability as a sunlamp, spectral ultraviolet radiation measurements were made in a laboratory selected by the Council. These measurements showed that the radiation of wavelengths shorter than 2,800 angstrom units is immeasurably small.

In this investigation the lamp was placed close in front of the quartz-fluorite achromatic spectroradiometer, and the spectral intensities were measured with a vacuum thermopile. The

relative spectral intensities (galvanometer deflections) corrected for absorption in the spectroradiometer are given in the accompanying table:

Wavelengths (Angstrom Units)	Relative Energy (Average of 3 Lamps) Microwatts per Square Cm.
3,132	7.96
3,024	2.59
2,967	1.15
2,894	0.28
2,804	0.09
Total	12.07

The radiation at 2,804 angstrom units (and shorter if measurable) is about 0.75 per cent of the total of all wavelengths, including 3,32 angstrom units and shorter. Mounted in an aluminum reflector the radiation at 2,804 angstrom units and shorter, relative to the total, would be still lower. Hence, these lamps comply with the Council's requirements for acceptability of a sunlamp for spectral quality of ultraviolet radiation.

Erythema Test: The untanned inner side of the upper arm, at a distance of 24 inches (61 cm.) from the lamp in an aluminum reflector, was exposed to lamp #12 on 108 volts for intervals of two, four, six, eight, ten, twelve and fifteen minutes. A mild erythema was obtained on six minutes' exposure. Exposures of eight minutes and longer were too long—the exposed part was still red after three days. With a standard voltage (115) and a modern reflector, the exposure time for an minimum perceptible erythema would be still shorter.

The lamp has been investigated clinically and found to be satisfactory.

The Council on Physical Therapy voted to accept the Sears S-4 Sunlamp for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

EHRLICH, OFTEN TERMED THE FATHER OF CHEMOTHERAPY, INTRODUCED THE USE OF BETTER ARSENICALS IN THE TREATMENT OF SYPHILIS. HE EARLY RECOGNIZED THE SPIROCHETICIDAL EFFECT OF ARSENOXIDE BUT DISCARDED IT BECAUSE OF ITS GREAT TOXICITY. IT REMAINED, THEREFORE, FOR AMERICAN WORKERS, TATUM ET AL. OF THE UNIVERSITY OF WISCONSIN, TO SHOW THAT A SIMPLIFIED DERIVATIVE OF ARSENOXIDE, HIGHLY PURIFIED, WAS EFFECTIVE AND RELATIVELY SAFE IN THE TREATMENT OF SYPHILIS. THIS PRODUCT WAS RECOGNIZED BY THE COUNCIL AND IS SOLD UNDER THE TRADE NAME OF MAPHARSEN. RECENT STUDIES HAVE BEEN MADE OF THE USE OF THIS LATER DERIVATIVE OF ARSPHENAMINE FOR CONTINUOUS TREATMENT OF SYPHILIS OVER A PERIOD OF DAYS (THE SO-CALLED DRIP METHOD). IN VIEW OF THE INTEREST IN THIS METHOD AND THE RESULTS WHICH HAVE BEEN REPORTED THE COUNCIL DEEMED IT ADVISABLE TO MAKE A PRELIMINARY REPORT AND AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT.

PAUL NICHOLAS LEECH, Secretary.

CHEMOTHERAPY OF SYPHILIS BY MASSIVE DOSE INTRAVENOUS DRIP

Great strides have been made in the treatment of syphilis, particularly in the last thirty-five years. At first, use of the mercurial preparations was elaborated. With discovery of Spirochaeta pallida, of the serologic tests for syphilis, of the specific arsenical preparations, and finally of the various bismuth salts, further great advances have been made.

Nevertheless, the fact still remained that it required a comparatively long time to get rid of the symptoms to such a point that the disease was not a menace to public health. This of course entirely ignored the effects of the disease on the patient. They were even slower to eradicate.

Various attempts have been made to find new specific remedies, and physical therapeutic agents using heat have been tried—none of them answering the problem.

It occurred to no one that perhaps by employing agents already at hand in a new form of attack it might be possible to exert greater effect on the disease.

It has remained for Chargin, Hyman, Leifer and Rice at the Mount Sinai Hospital perhaps to find such a loophole, utilizing intravenous drip therapy.

Hyman and his collaborators¹ have shown that when active or inert chemicals, drugs and biologic fluids are injected intravenously in a rapid manner they may give rise to alarming symptoms and may at times even be fatal—so-called speed shock. The animals studied showed rapid fall of blood pressure, sometimes fatal, with dyspnea, and noncoagulation of the drawn blood. These investigators found that even when simple saline solutions were employed, if there was fatality, necropsy showed multiple punctate hemorrhages of the viscera and atelectasis or emphysema of the lungs with thrombi of the veins. Experimentally if they regulated the rate of flow of the preparation by means of intravenous drip so that not more than 2 or 3 cc. a minute was injected, even toxic substances such as histamine could be introduced without difficulty.

Experiments were tried in man with the intravenous drip for physiologic solution of sodium chloride, dextrose and citrated blood, and it was thought by the authors that it might even be possible to employ potent agents in greater doses than have been employed in the past without severe reactions or damage to the host. Chargin² felt that the method might be applied to the administration of larger doses of arsenicals than are ordinarily employed in the treatment of early syphilis, and in 1933 Chargin, Leifer and Hyman³ treated twenty-five persons who had early syphilis by means of the intravenous drip given in the form of solutions of 4 Gm. of nearsphenamine over a course

solution 5 per cent, and these alternate doses were employed until the total dose had been administered for the day, so that in a period of fifteen hours the patient would have received 1,500 cc. of 5 per cent dextrose solution and 1 Gm. of nearsphenamine.

Toxicology.—Primary Herxheimer fever was noted in 57 per cent of the patients. The average height was 102, and the highest temperature recorded was 105 F. The longest duration of febrile reaction was four days. A secondary fever appearing toward the latter part of the therapy was noted in 63 per cent of the patients.

Toxicodermas.—Scarlatiniform, morbilliform or erythema multiforme-like toxicodermas occurred in forty patients. An additional four patients developed toxicodermas in the follow-up. One patient developed a desquamation of the skin. A true dermatitis exfoliativa occurred once and was followed by complete recovery.

Peripheral neuritis occurred in 38 per cent of the patients and lasted as long as from four to six months. There seemed to be no relation between arsenic excretion or retention and the neuritis. There were no symptoms of damage to the kidneys. Four patients developed mild jaundice. Seven patients had an icterus index that exceeded 10. Five had a later secondary icterus index of 15 or more. A hemorrhagic tendency developed five weeks after the treatment in one of the early patients, and it was found that he had a thrombocytopenia, which was cured by splenectomy. Two patients exhibited cerebral symptoms suggesting a hemorrhagic encephalitis, and one of them died. It was noteworthy that nitritoid crises, various types of atrophy and degeneration of the liver, aplastic anemia and pulmonary embolizations were absent as toxicologic phenomena.

Arsenic Excretion Studies.—Analyses of the total urine and feces in twelve unselected cases showed that 20 per cent was excreted in the urine and 32 per cent from the feces during the course of therapy.

Clinical Results.—The patients showed rapid healing of the primary and secondary lesions. Darkfield studies became negative invariably in twenty-four hours. All of the patients showed good appetites and many showed gain in weight.

Effect on Serum Reaction.—These patients were checked very carefully from the standpoint of serologic reactions, and sixty-seven, 86 per cent, who were adequately followed showed complete seroreversal. Comparison of the first series with the series reported in this paper showed that the nitritoid crisis was not observed in any case. Polyneuritis was present in 32 per cent of the first and 38 per cent of the second series. Administration of vitamin B to the patients did not lessen this symptom, nor did vitamin C protect any of the patients in the second series from secondary fever.

The clinical results were quite parallel in the two series. Serologic reversal was obtained in approximately 90 per cent of both groups. There were five acknowledged failures. In the first group one patient with inadequate therapy, 2.9 Gm., had persistent seropositivity at his last visit at four months. In the second group two clinical relapses and two serologic relapses were reported.

Because of the importance of the entire problem and of the results obtained, it was thought best to gain the help and advice of public health authorities, of several foundations, and of clinicians in other institutions and in other capacities, and a Committee on Massive Drip Intravenous Therapy was formed.⁴

The committee has since made available an outline of massive dose chemotherapy of early syphilis by the intravenous drip method. Because of the toxic symptoms noted after the use of nearsphenamine, it was decided to employ mapharsen. At first this was used in small doses, but because of the frequency of relapses and the lack of toxic symptoms the dose was gradually increased to 1.2 Gm. of mapharsen in a course of five

Toxic Effects

	Nearsphenamine	Mapharsen
Total treatment courses.....	111	283
1. Primary fevers	69 (62%)	115 (41%)
2. Secondary fevers	71 (64%)	35 (12%)
3. Toxicodermas	50 (45%)	32 (11%)
4. Dermatitis exfoliativa	1* (0.9%)	0
5. Blood dyscrasias	0	0
6. Renal damage	0	0
7. Jaundice	4 (3.6%)	2 (0.7%)
8. Peripheral neuritis	39 (35%)	5 (mild) (1.7%)
9. Cerebral symptoms (total).....	2 (1.8%)	3 (1.06%)
a. Hemorrhagic encephalitis...	1 (0.9%)	1 (0.35%)
b. Single convulsion	1 (0.9%)	1 (0.35%)
c. Disorientation	0	1 (0.35%)
10. Fatality	1 (0.9%)	0

* Received sulfanilamide for complicating gonorrhea.

of five days. Five of these patients were not followed beyond the fifth month of the first year. The remaining twenty patients all showed complete serologic reversals, though five were not followed a sufficient time for satisfactory observation. Fifteen were examined on or about the fifth year. Eleven of these had repeatedly negative Wassermann reactions. Two of the fifteen had become reinfected with syphilis, one of these instances being indubitable and the other highly presumptive. It was felt that the results had been so promising that a further study should be made, and eighty-six men were used, the average dose of nearsphenamine being slightly in excess of 4.1 Gm. and the duration of treatment slightly less than five days.

The technic employed was similar to that first used: First an intravenous drip of 100 cc. of a 5 per cent dextrose solution; at the end of an hour a solution of 0.1 Gm. of nearsphenamine dissolved in 50 cc. of 5 per cent dextrose solution was used; this in turn was followed by another hour of plain dextrose

days, i. e. 0.24 Gm. daily, and, instead of alternating an hour's use of 5 per cent dextrose solution with an hour's treatment of the mapharsen solution, 10 mg. of mapharsen is dissolved in 100 cc. of 5 per cent dextrose solution and administered simultaneously. The usual procedure is to prepare 600 cc. of such solution, containing 60 mg. of mapharsen, enough for three hours of treatment. When the apparatus containing 2,000 cc. of 5 per cent dextrose is used, a total daily dose of 0.24 Gm. of mapharsen is prepared the first thing in the morning and the solution is administered over a ten to twelve hour period. This simplifies the technic to a great extent. The hourly dose consists of 0.02 Gm. in 200 cc. of 5 per cent dextrose solution.

Variants in the usual procedure: A. There is a primary fever on the first day and therapy is stopped if the temperature reaches 101.4 F. or more. This usually happens by the sixth to the eighth hour. This insufficient dose is compensated for in the following manner: First day 0.12 Gm. of mapharsen is administered; on the second, third and fourth days 0.28 Gm. of mapharsen; on the fifth day 0.24 Gm. of mapharsen.

B. When clinical jaundice appears in the course of the treatment the procedure is interrupted. This has been seen but once in all of the cases.

Insufficient time has elapsed since the use of mapharsen to justify a final estimate of its effects as compared to those of neoarsphenamine. The toxic effects in the neoarsphenamine and mapharsen series are given in the accompanying table.

It is to be noted that there have been only five cases of peripheral neuritis (and mild) with the mapharsen (1.7 per cent), as against thirty-nine (35 per cent) with the neoarsphenamine. Primary fevers are lower with mapharsen than with neoarsphenamine; secondary fevers usually appear the evening of the last day of therapy and generally return to normal in a matter of a day or so. There were only one fifth as many of the latter with mapharsen as with neoarsphenamine. Toxicodermas in the form of a morbilliform or urticarial eruption were again only a fourth as many with mapharsen as with neoarsphenamine. While there were no cases of death from hemorrhagic encephalitis with mapharsen, nevertheless one of the patients developed convulsions two days after termination of therapy and lapsed into a stupor, in which he remained for forty-eight hours. The other two cases of cerebral symptoms were mild, one with a single convulsion and prompt complete recovery, the other showing merely a state of mental confusion. This type of reaction, however, which is one of the most dreaded of the arsenical complications, is apparently seen with mapharsen as well as with neoarsphenamine. Fortunately there was no fatality with mapharsen.

It may not be amiss to mention some later work along the same line investigated by Tzanck and his collaborators.⁵ Working on the idea of Pollitzer's three daily maximal doses of an arsenical, he has devised the scheme of utilizing these doses in far larger amounts but by the same intravenous drip method which has been discussed. The claim is made that this work is entirely independent.

These investigators have treated 157 patients with neoarsphenamine by a drip method, 0.01 Gm. per minute, 1.5 Gm. a day for three days. They report that the lesions disappear rapidly; that mucous patches disappeared in two or three days; that the spirochetes could not be found after one day. The serologic reactions are reported to be almost always negative in less than two months, even in two weeks in some cases.

The technic consisted in the use of 0.01 Gm. of neoarsphenamine per cubic centimeter of physiologic solution of sodium chloride, one drop given every three seconds. A light rise of temperature was observed early in therapy. No nitritoid reactions were observed. Patients were then given two months of bisulphite therapy and another three days of arsenical treatment as described. No details are given as to follow-up and

study of the patients, and at least as far as publications are concerned this work does not show the care and detail used by the Mount Sinai group.

COMMENT

The work carried on by Tzanck and his co-workers in principle at least resembles the investigations of Chargin, Hyman, Leifer and Rice. Both aim at Ehrlich's idea of "therapia magna sterilisans." Nevertheless, the American workers prefer that their project be considered by itself. It is true that they also have priority. Moreover, their cases have been far more carefully studied preliminary to as well as throughout the investigation, and follow-up on their cases has been of the best possible. Thus the early studies of Hyman and his collaborators on influence of velocity in intravenous injection were carried on from 1931 to 1935, and as early as 1933 Chargin and his co-workers utilized these principles in the use of arsphenamine in massive doses for the treatment of syphilis. The work of Tzanck and his co-workers first appeared in 1938 and, while it was claimed to be entirely independent, nevertheless it utilized the principles of the intravenous drip.

The principle of this new advance in syphilotherapy is based on the ability through continuous drip therapy to utilize doses of arsenicals far larger than can ordinarily be safely administered to human beings. The results with the first twenty-five cases treated in 1933 were promising, so promising that a larger group of patients, eighty-six, were treated with neoarsphenamine. Arsphenamine was not found to be practicable because of irritation of the vein walls. Response to therapy was gratifying, lesions healed rapidly, spirochetes disappeared in less than twenty-nine hours. Of the patients adequately followed, 86 per cent showed complete seroreversal. There were five acknowledged failures in the two groups. From the standpoint of reactions a peripheral neuritis, lasting from four to six months, was noted in about one third of the cases. Moreover, 2 per cent of the patients had cerebral symptoms suggesting hemorrhagic encephalitis, and one of them died. Nitritoid crises, severe liver damage and aplastic anemia were notable by their absence. Nevertheless the frequency of toxic symptoms was so high that the group, in consultation with the larger group already mentioned, thought it best to utilize another arsenical, mapharsen. This arsenical has been used in 283 further cases. In the earlier ones the dosage was too small, resulting in a certain number of relapses. The dose now being employed, 0.24 Gm. of mapharsen a day for five days, is giving a satisfactory clinical result, although the time elapsed is too short to predict what the final five year results will show. There has been a notable drop in toxic effects as compared to those seen with neoarsphenamine. Yet one of the dreaded complications, hemorrhagic encephalitis, was still noted in three of 283 cases. Fortunately, only one of these was severe. No fatalities resulted from the use of mapharsen.

The public health aspects of this new departure in syphilis therapy are tremendous in their possibilities of rapid sterilization of early contagious syphilis. On the other hand, results in syphilis therapy cannot be determined over night, and a system that still gives evidence of possible hemorrhagic encephalitis in one of apparently every hundred cases treated is by no means a foolproof procedure.

In the opinion of the Council on Pharmacy and Chemistry the work of Chargin, Hyman, Rice and Leifer with continuous intravenous drip massive doses of arsenicals in the treatment of early syphilis offers great possibilities. In view of the frequency of toxic reactions, some of them grave in type, the Council believes a conservative attitude of the medical profession to be advisable. Such a form of syphilis therapy is still in the experimental stage and should be confined to large university and public health clinics or suitable hospitals organized to carry on this project on a recognized experimental plane. It may well be that animal experimentation may also do much to assist in answering the question. In the meantime the entire medical profession will follow with great interest the further evolution of the situation.

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

INFLUENCE OF A PUBLIC HEALTH PROGRAM ON A RURAL COMMUNITY

Fifteen years ago the Commonwealth Fund, together with local and state government agencies, established a demonstration of rural public health work in Rutherford County, Tenn. At about the same time other health demonstrations were begun in other areas. Many of these demonstrations have lapsed. Some of the communities in which they function are not noted for the present quality or completeness of their public health services. Not so with Rutherford County. The work there has been continuous though unspectacular. It has been supported by local funds, which at the peak in 1929 accounted for approximately 85 cents out of a total per capita cost of \$1.20; in 1933, the lowest point since the peak, such funds accounted for approximately 55 cents out of an annual expenditure of 90 cents per capita. The remainder has come from state funds and other contributions, largely from the Commonwealth Fund.

A booklet¹ now published by the Commonwealth Fund reviews fifteen years of public health work in Rutherford County. Syphilis has increased 100 per cent in cases reported in the five year period 1934-1938 as compared with the period 1924-1928; the increase in gonorrhea reported in the same length of time has been almost 700 per cent. The syphilis clinics are crowded. Of the persons under treatment 73.6 per cent have had at least twenty treatments of arsenic and twenty of a heavy metal in the last year. Although a considerable number of lapses in treatment occur, the health department nursing staff succeeds in returning a high percentage for further treatment.

One of the paradoxical developments which indicate the necessity for caution in evaluating the effect of public health measures is that in Rutherford County, with a preschool population of which 65 per cent has been immunized against diphtheria, the disease has declined less rapidly than in four adjoining unorganized counties² in the period 1927-1938. In general, however, a comparison of Rutherford County with these four adjoining counties and with the state of Tennessee is favorable. For example, the death rate in the five year period 1934-1938 for typhoid was 1.8 for Rutherford County, 16.0 for the adjoining counties and 5.5 for the state. Other rates were as follows:

	Rutherford County	Unorganized Counties	State of Tennessee
Measles	3.7	6.1	5.4
Influenza and pneumonia....	119.6	161.6	139.9
Diarrhea and enteritis under 2 years	14.2	20.8	21.1
Stillbirths	33.3	43.9	38.6
Infant deaths	43.6	61.2	64.4
Maternal deaths	4.4	6.3	6.1

For scarlet fever the situation is reversed, with a death rate of 2.5 in Rutherford County as compared with 1.0 for adjoining counties and 1.1 for the state. The tuberculosis death rate of 87.6 is practically identical with that for the state, whereas in the adjoining counties the corresponding rate is 100.3.

Among the significant features of the Rutherford County program is its contribution to the training of public health personnel. It has been used as a public health laboratory, having trained in its last ten years a total of 518 undergraduate medical students, 101 practicing physicians and eighty-three physicians in public health work. At the same time it has trained in public health 137 undergraduate nurses and 112 graduate nurses. Three sanitary inspectors have been given postgraduate instruction.

This work shows what can be done in a more or less typical Southern rural county by enlisting available local and state facilities plus outside help. The outside aid has been given with wisdom and discretion, as indicated by the high percentage of reliance on local

1. Walker, W. F., and Randolph, Carolina R.: *Influence of a Public Health Program on a Rural Community*, New York, Commonwealth Fund, 1940.

2. Bedford, Cannon, Coffee and Marshall.

funds. Supplementing the outside financial aid, of course, has been the technical advice available from the expert consultants of the Commonwealth Fund and those whom they have called to their assistance. The report reflects throughout a state of excellent cooperation between medical facilities in the community and the public health service. The Rutherford County demonstration has continued for fifteen years and is no longer in the demonstration phase but is an integral part of the community life; it is periodically evaluated by competent and objective experts; no excessively optimistic claims are made for it. This project has, moreover, made a significant contribution to the solution of one of the most important problems in public health today: the training of specialized personnel.

ALLOTMENT OF FEDERAL FUNDS FOR VENEREAL DISEASE CONTROL

The Surgeon General of the United States Public Health Service, with the approval of the Federal Security Administrator, has recently issued regulations under which federal funds for carrying out the Venereal Disease Control Act are to be distributed for the fiscal year 1941.¹ Federal grants-in-aid totaling \$5,672,388, or 88.8 per cent of the \$6,200,000 appropriated,² will be allotted, compared to \$4,379,250 which was allotted for 1940.³ Allotments amounting to 26.7 per cent of the money available will be made to the states in the ratio in which the population of each state bears to the population of the United States as shown by the Census Bureau 1937 midyear population estimates. Allotments amounting to 35.3 per cent of the available amount will be made to the states on the basis of (1) the varying composite geographic and racial prevalence rate for syphilis, (2) the varying costs of providing "equal services," (3) the need for training centers and demonstrations in selected areas and (4) the need for facilities to prevent and control venereal diseases in localities where armed forces or civilian employees engaged in national defense activities are concentrated. Allotments amounting to 26.7 per cent of the available appropriation will be made to the states on the basis of financial need, which is determined to be the ability of the state to raise revenue expressed indirectly in terms of differences in per capita income. A state, to be eligible to receive a grant-in-aid, must submit to the Surgeon General (a) a comprehensive statement of its existing venereal disease control organization, program and budget; (b) a proposed plan for improving the service of its venereal disease control unit including provision for a merit system of personnel administration, provided that the state agency may exempt, among other persons, all part time professional persons not engaged in the performance of administrative duties who are paid for any form of medical, nursing or other professional service and who

meet the standards of training and experience established by the responsible state authority; (c) specific plans for the control of gonorrhea; (d) a proposed plan for extending and improving district, county and city venereal disease control services for both gonorrhea and syphilis, and (e) a statement indicating the ways in which the proposed expenditure of federal funds may be expected to stimulate permanent progress in the prevention and control of venereal diseases in both urban and rural areas. In its plan a state may provide for training, for a period not to exceed one year, professional and technical personnel so as to qualify them to conduct venereal disease control work effectively, provided the funds used for this purpose and the scientific personnel nominated for training are first approved by the Surgeon General. Expenditures can be made only for the purposes specified in budgets approved by the state health officer and the Surgeon General. The state health officers of states receiving grants-in-aid are required to make quarterly and annual financial reports to the Surgeon General and to submit to him certain progress reports, including a semiannual report on the status of venereal disease control activities in the state, a monthly clinic report for each clinic treating venereal diseases, a monthly state morbidity report and a monthly city morbidity report for each city with a population of 200,000 or over.

As announced in the regulations, a state or territorial plan to be acceptable must make available minimal services for the control of venereal diseases which are substantially in accord with the standards that are prescribed. Any laboratory, state or otherwise, receiving federal funds must demonstrate by a suitable method that the serologic tests performed have a satisfactory sensitivity and specificity rating and it must provide laboratory services for venereal diseases on the same basis as it does for other communicable diseases. Free diagnostic and treatment facilities for both syphilis and gonorrhea must be provided, by all health departments or clinics receiving federal funds, for (1) the diagnosis and emergency treatment of all patients who apply, (2) all patients referred by a private physician either for continued treatment or for consultative advice and opinion, and (3) all patients unable to afford private medical care, provided:

That in communities where other adequate facilities for the diagnosis and treatment of gonorrhea or syphilis are available, funds may be reallocated in the discretion of the state health officer independently to the gonorrhea or syphilis departments of polyclinics in order to provide complete clinical service.

The ability of a patient to pay for private medical care is to be determined by the state or local health department or by welfare agencies. Antisypilitic drugs must be distributed free on the request of any physician duly authorized by law to administer such drugs. Diagnostic and treatment services must be as freely available to infected residents of other states and counties as to people who reside in the governmental unit providing the services. The services of a properly qualified full-

2. Public No. 665, 76th Congress.

3. 4 Federal Register 2163.

time venereal disease control officer must be provided in each state and in each municipality if the population of either exceeds 500,000 on the basis of the 1930 census. In reallocating funds for local venereal disease control services the state health officer is required to give due consideration to the relatively higher prevalence of syphilis and gonorrhea in urban areas.

In general these regulations differ but little from those promulgated for venereal disease control for the fiscal year 1940.³ The new regulations, however, allot to the several states and the territories for the fiscal year 1941 federal grants-in-aid exceeding by over \$1,290,000 those allotted for the fiscal year 1940. The only provisions in the new regulations not contained in the prior regulations which are of particular interest to the medical profession are those set forth relating to the establishment of state merit systems of personnel administration and the proviso, as quoted, qualifying the furnishing free of facilities for diagnosis and treatment to all patients unable to afford private medical care for venereal diseases.

POISON IVY DERMATITIS

Rhus poisoning, the active principle of which is the complex radical urushiol, ranks highest among the causes of plant dermatoses and constitutes an occupational hazard for horticulturists, farmers and those engaged in clearing land, not to mention the infection of carefree ramblers in the woods. Though many efficacious methods exist for treating the eruption after it has occurred, little has been accomplished for prophylaxis. Potassium permanganate and ferric chloride discolor and pigment the skin; desensitizing injections of ascending doses of rhus toxin seem to be impracticable, if large numbers of field workers are involved.

An alkaline vanishing cream containing a nonirritant, nonstaining oxidizing agent such as sodium perborate or potassium periodate is now recommended¹ as an effective preventive against poison ivy dermatitis. By incorporating either of these drugs in an ointment and applying it to the skin of the arms and the face before exposure, even those who are previously ascertained to be highly susceptible may be effectively protected. Preliminary tests on a limited number of volunteers with a 10 per cent sodium perborate ointment, to which a poison ivy extract of well known manufacture representing a concentration fifteen times greater than that of the toxin in the fresh leaf was applied, failed to elicit reactions. Only a slight erythema, about one fourth of an inch in diameter, manifested itself at the site of application in one member of the group who was most susceptible to the reaction. Other tests made to determine the respective participation of the alkali and the oxidizing agent in the detoxicant action on rhus poison showed that the irritant principle of poison ivy was inactivated by the oxidant.

After satisfactory performance in the laboratory, the prophylactic cream was tested by actual contact and

handling of poison ivy foliage. The hands and right forearms of two of the group, including the most allergic subject, were anointed with the preparation and they were set to plucking poison ivy leaves growing around a tree. In addition, the leaves were pressed against the cream-protected areas of their forearms, brushed up and down against them and allowed to remain as long as half an hour in contact. An hour later the cream was washed off with soap and water. Reactions did not occur despite the fact that the more susceptible of the two had contracted a linear vesicular eruption on an unprotected area of his arm from accidental contact with poison ivy while undergoing the test.

The United States Public Health Service, which developed this technic, recommends that vanishing creams containing oxidizing agents such as those referred to be prepared for use at least every two weeks to avoid deterioration. They should be rubbed well into the skin of the arms and face before each exposure. Soap and water used to remove the deposit of the powdered oxidant on the skin will emulsify it and wash away whatever toxins are lodged in the pores or on the skin.

Current Comment

MEDICAL APPLICATIONS OF "ATOM SMASHING"

Radioactivity has already contributed enormously to medical progress. Now it seems rational to believe that the consequences of "atom smashing" may further affect medicine in numerous ways. As pointed out by Solomon,² the new radioactive elements cannot be administered to human beings just as they come from the cyclotron or from any other atom smasher but must first be purified and then synthesized into some compound which is easily taken into the body. The possibilities of use, however, are illustrated by the fact that of the ninety-two known stable elements eighty-seven may be made radioactive artificially. Furthermore, they possess half-lives which are short in comparison with that of radium. Thus the intensity of radiation of radioactive phosphorus, for example, diminishes by half in the course of fourteen days. Obviously if some substance such as radioactive phosphorus proves to be therapeutically effective in any disease, its rapid decrease in activity would make its internal administration far less dangerous than that of radium. The most encouraging results in the application of such radioactive elements have been produced in the treatment of leukemia: one patient is reported to have been kept alive by the administration of radioactive phosphorus after x-ray treatment could no longer be applied. Although such observations are far too few from which to draw conclusions, the possibilities of administering radioactive substances without the attendant dangers of radium and x-rays are encouraging. The further pursuit of such therapeutic objectives is the combined problem of scientists working in many different fields.

FIVE DAY TREATMENT OF
EARLY SYPHILIS

Elsewhere in this issue of THE JOURNAL appears a report by the Council on Pharmacy and Chemistry of the American Medical Association relative to the so-called five day treatment for early syphilis. This treatment developed from the observation by Hirschfeld, Hyman and Wanger¹ that numerous chemical compounds could be safely administered to animals and human beings in amounts far exceeding the usual toxic doses by a slow continuous intravenous drip injection of dilute solutions. This manuscript was first made available in 1931. Since 1933 a considerable number of papers have appeared dealing with this technic as applied to the treatment of early syphilis by a group of workers² at the Mount Sinai Hospital of New York. A number of manuscripts have been read since that date before various meetings. Obviously there are considerable advantages in any method of treatment of syphilis which can be completed in a brief period of time, so that the results, if even approximately comparable to those obtainable with systems of treatment requiring months or years, are likely to bespeak for such a method the most favorable consideration. However, there must be borne in mind as well the fact that the employment of remedies with such a technic involves a certain amount of risk and that the risk with drugs of the type of neoarsphenamine and mapharsen is far greater than that with less toxic preparations. There seems to be a chance equivalent to about one in a hundred that patients treated with this technic with either drug may develop in a more or less severe form one of the most serious of all arsenical reactions—hemorrhagic encephalitis. This risk seems to be far greater with this method of treatment than with the conventional use of divided doses. Moreover, in patients treated by this technic, peripheral neuritis was encountered in 35 per cent of patients given neoarsphenamine and in 1.7 per cent of those given mapharsen by the intravenous drip method. Fevers and toxicodermas also occurred. Obviously, many more studies will need to be made both of patients under controlled conditions in hospitals and of animals in the laboratory to establish definite criteria for the use of this new technic. The method is still in an experimental stage. Its importance cannot be gainsaid, and the possibility of great advances in the practical treatment of syphilis by this or a similar technic is so important that it is to be hoped that research will be expanded and intensified so as to yield positive conclusions at the earliest possible moment.

VITAMIN C IN STRAWBERRIES AND
CABBAGES

Newer data on the vitamin C content of fresh fruits and vegetables reveal that many of these foods are even richer sources of the antiscorbutic factor than any one had supposed. The luscious strawberry and the humble cabbage now are found to rank with citrus fruits as foods which can provide in a single serving enough vitamin C to meet the daily requirement for this dietary essential. Such observations have been made possible by the perfection of chemical methods for the rapid determination of vitamin C in biologic materials. The use of chemical methods for the estimation of ascorbic acid has proceeded from the biochemical research laboratories to many other fields. Some members of the canning industries find that it is advantageous to check in a routine manner the vitamin C content of products such as canned tomato juice, long recognized as an important source of vitamin C. A recent commendable trend has been the investigation of the vitamin C content of different varieties of tomatoes, oranges and other important sources of vitamin C. Satterfield and Yarbrough¹ determined the ascorbic acid content of several varieties of strawberries produced under nearly identical conditions. They report considerable variation, but all varieties of the strawberry may be considered to be rich sources of vitamin C. They found on the average from 36 to 65 mg. of ascorbic acid to each hundred grams of fresh berries. Burrell, Brown and Ebright² likewise report considerable variation in the ascorbic acid content of thirty-one varieties of cabbage. The lowest average value reported was 48 mg. for each hundred grams of fresh cabbage and the highest was 181. From these studies it may be concluded that, to supply a fairly liberal daily allowance of vitamin C, equivalent to 1,000 units or 50 mg. of ascorbic acid, it would be necessary to consume only from 77 to 138 Gm. of strawberries (about 3 to 5 ounces) or from 28 to 104 Gm. of fresh cabbage (about 1 to 4 ounces). Many other foods, such as potatoes, spinach and turnips, contain large amounts of vitamin C, so that it is not surprising to note that little evidence of vitamin C deficiency has been observed among the adult population of the United States. The vitamin C requirements of the adult may be supplied by a small portion of coleslaw or by about thirty strawberries. The time may come when foods will have to be selected for their contribution of dietary essentials. It will be necessary to know not only the relative amounts of ascorbic acid in different foods but also the contribution which different varieties of each food may make and the effects of processing, storage, cooking and perhaps even environmental conditions during the growing season. Agricultural economists may well begin now to give attention to the amount of vitamin C produced in calculating the yield of certain crops to the acre.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PHYSICAL THERAPY IN THE MILITARY SERVICE

JOHN S. COULTER, M.D.
Chicago

In considering the place of physical therapy in the army during a war it is interesting to summarize a general description of the medical service in the theater of operations, the zone of communications and the zone of the interior. This summary will show that in the present duties and relations of the medical service there is no provision for physical therapy except in the zone of communications and the zone of the interior. The general mission of the medical service is:

(a) The preservation of the strength of the forces in the field.

(b) The care and treatment of the sick and injured men so that casualties may be more promptly returned to duty.

The specific duties of the medical service are:

(a) The initiation of sanitary measures to insure the health of the troops.

(b) The care of sick and wounded men in camp, on the march, on the battlefield and after removal therefrom.

(c) The methodical disposition of sick and wounded so as to insure the retention with the fighting forces of effectives and to relieve it of noneffectives.

(d) The transportation of sick and injured.

(e) The establishment and operation of hospitals, dispensaries and other installation necessary for the care of sick and injured.

(f) The supply of material necessary for the prevention of disease among troops and for the care of the sick and injured.

(g) The preparation and preservation of records of sickness and injury for the immediate information of higher authority, and assistance in the adjudication of claims with justice both to the government and to the individual.

(h) The direction and supervision of all public health measures among the inhabitants of occupied territory.

One of the assigned duties of the Medical Department is the evacuation of the sick and wounded in all theaters of operations. The difficulties and magnitude which this task may assume should be understood by all concerned. In the operation of a large force against strong resistance, as much as one fifth of the troops may have to be evacuated from the combat zone to the communications zone in a relatively short period. This movement of noneffectives from the combat zone is properly conceived as being in the nature of a withdrawal. Its execution is a responsibility of the medical service. The evacuees are unorganized, are non-self supporting and are gathered individually from all units of the field forces. They require individual care, treat-

ment and handling through all the stages of their withdrawal from points in the forward area to the hospitals of the communications zone.

The present Regular Army division, sometimes called the Streamline and also the Triangular Division, has a medical battalion instead of a medical regiment. The medical battalion has in general a similar organization to that of a regiment. It requires less personnel, since the Regular Army division now has a strength of approximately 12,500 instead of the former 20,000.

In battle the medical regiment completes the division medical service by evacuating battalion and regimental aid stations to collecting stations (and when necessary clearing the field of wounded) by its collecting battalion. The ambulance battalion transports the sick and wounded from the collecting stations, or from points farther to the front, to the clearing station. The hospital battalion establishes and operates the clearing station, sorting, treating and otherwise preparing the patients for return to their units or for evacuation out of the division area.

Ordinarily there are assigned to one field army, in addition to other units, eight surgical hospitals, ten evacuation hospitals and one convalescent hospital.

SURGICAL, EVACUATION AND CONVALESCENT HOSPITALS

A surgical hospital is designed for the initial care of the so-called nontransportable wounded; that is, those wounded whose condition is so serious as not to permit of their immediate removal from a clearing station to an evacuation hospital.

The evacuation hospital has a normal capacity of 750 beds and receives its patients from the clearing stations and surgical hospitals established in the combat zone. Evacuation hospitals are primarily for use during battle, but they may also be established to receive sick and injured from concentration or rest centers and from large marching columns when station hospitals or general hospitals are not available for this purpose. When battle is imminent, evacuation hospitals in sufficient number to meet expected needs (usually about one for each front line division) are located and opened.

The convalescent hospital has a capacity of 3,000 beds and is designed for slightly ill and convalescent patients. It plays an important role in the conservation of the troop strength of the combat zone.

The surgical, evacuation and convalescent hospitals are all in the theater of operations. One of the most important duties of the medical department is the evacuation of the sick and wounded in all theaters of operations. The medical facilities and services in the theater of operations are such that physical therapy cannot be started in the hospitals of this zone of operations.

THE GENERAL HOSPITAL

In the communications zone the most important hospital unit is the general hospital. In a communications zone with six field armies in the theater of oper-

ations there would be authorized 300 general hospitals for the communications zone. The number of general hospitals allotted to the communications zone would depend on the location of the communications zone in relation to the zone of the interior, the extent of the zone and the number of troops involved. Under certain conditions there may be no need for general hospitals in the communications zone, while under other conditions, such as with an oversea expeditionary force, a large number may be required.

The general hospital is a fixed unit of 1,000 beds capacity, designed for the treatment of all cases arising within the theater of operations and located a sufficient distance from the combat zone so that military reverses will not disturb their operation. Its equipment is adequate for the care of all cases of whatever severity. Although designed for the definitive treatment of cases, it will be necessary in a prolonged campaign to evacuate patients from these general hospitals to general hospitals in the zone of the interior, especially those who are not likely to be fit for service for a considerable time or who will be incapacitated permanently for further military duty.

General hospitals should be located at points which afford good rail or water connection with regulating stations and with the zone of the interior. The presence of suitable buildings and utilities is most advantageous, but additional construction will usually be required. In planning construction, consideration should be given to the availability of near-by landing fields for airplane ambulances.

General hospitals, when conditions permit, are organized into groups of from three to ten. This group is called a hospital center. Each hospital center contains a convalescent camp, which normally will have a bed capacity equivalent to 20 per cent of that of the center. Patients who no longer require careful hospital treatment but who are not yet fit for duty will be transferred to this camp, where they are prepared for duty by a system of graduated exercises.

PHYSICAL THERAPY

As the equipment of a general hospital should be adequate for the care of all cases of whatever nature or severity, it is here that physical therapy should be started in the care of many fractures, dislocations, wounds and amputations. In individuals suffering from trauma, physical therapy is most effective if started early in the general hospitals of the zone of communications and continued in the general hospitals of the zone of the interior. In the First World War physical therapy was started in the general hospitals and hospital centers of the army of the United States in France and was most effective in reducing the length of temporary disability and the amount of permanent disability.

The Surgeon General of the Army recently stated that it would be the policy of the Medical Department of the Army in the next war to discharge all wounded men requiring prolonged hospitalization to the Veterans' Administration for treatment in its hospitals. This would mean that the care of cases requiring long hospitalization by the Veterans' Bureau would lessen the number of army general hospitals in the zone of the interior. At the same time this would not lessen the number of wounded in the country which require physical therapy.

In any event an estimate of 300 general hospitals of 1,000 beds each for six field armies in a war of such

severity as is occurring in Europe would not seem to be excessive. Proportionately, in comparison with civil hospitals with the same number of beds an army general hospital physical therapy department will need a medical director and at least six physical therapy technicians.

The Committee on Medical Preparedness of the American Medical Association recently sent to each physician in the United States a questionnaire about service in the Army, Navy or Public Health Service during an emergency. The questions about special medical societies and specialists follows the listing in the American Medical Directory. Therefore under question 68: "Are you a member of any special medical societies?" physical therapy is not listed but there is a place where physicians specializing in physical therapy can insert "Society of Physical Therapy Physicians."

Under questions 60 to 63 physical therapy is not listed, but it can be added under 60:6, and question 75 and 76 "Service you consider yourself best qualified to perform" can be answered by those physicians specializing in the subject of physical therapy. The committee is listing physical therapy physicians as a group.

It is not surprising that physical therapy is not listed as a specialty. In 1938 a group of physicians interested in physical therapy organized a special society for physicians specializing in physical therapy, The Society of Physical Therapy Physicians. The requirements for membership in this society are that members "shall have been engaged in the practice of physical therapy for at least five years" and "shall have given evidence of satisfactory scientific attainments."

In 1940 this society has a membership of thirty-eight and a waiting list of ten. Therefore the American Medical Association is justified in not listing physical therapy as a specialty. There are other subjects not listed, such as allergy and cardiology.

For these and other reasons it should be clear that there is a shortage of at least 250 physicians qualified to take charge of physical therapy departments in a general hospital of 1,000 beds.

The Northwestern University Medical School for the last ten years has been offering to qualified graduate physicians a month's course in physical therapy. It is felt that this course serves as a substantial foundation for the intelligent application of physical therapy. The instruction consists of lectures on the physical and therapeutic principles of the physical agents and their physiologic effects, the observation of patients, the preparation of physical therapeutic prescriptions, the demonstration of technic, the attendance at clinics and the actual treatment of patients under supervision. Such a course established at many other medical schools where there is a qualified physician in charge of the physical therapy department could give the necessary basic training to physicians to be assigned to physical therapy departments of general hospitals which are to serve the military establishment.

A physician with a year's internship and at least a year's approved residency can in this month's course secure a groundwork in physical therapy that will enable him in the event of an emergency to take charge of the physical therapy department of an army general hospital. This course has been given for the last ten years. Physicians completing this course have taken charge of the physical therapy departments of twelve medical schools in the United States. With this experience it is believed that this length of a course will serve

during an emergency. It would seem desirable that some provision be made to train medical officers in such short courses as the need arises. At least ten medical schools and the Mayo Clinic have facilities to give such courses as described.

The shortage of physical therapy technicians is even more acute. At present there are 1,029 senior registered physical therapy technicians on the roster of the American Registry for Physical Therapy Technicians. The American Physiotherapy Association has a membership of 1,017. About 75 per cent of the American Registry for Physical Therapy Technicians are included in the membership of the American Physiotherapy Association. There are therefore about 1,274 trained physical therapy technicians in the United States. These technicians are all employed in hospitals, private offices or schools for crippled children or in the state program services for crippled children, sponsored by the Crippled Childrens' Division of the Children's Bureau of the Department of Labor.

It would be a great mistake to lower the educational standards for physical therapy technicians. This need not be done if training is started at once. The minimum curriculum as given by the Council on Medical Education and Hospitals of the American Medical Association requires 1,200 hours. It is believed that the 400 hours required for clinical practice could be given in the approved school for physical therapy technicians or in a hospital physical therapy department in charge of a senior registered physical therapy technician. Therefore a course could be given at an approved school of forty hours a week for twenty weeks provided the 400 hours of clinical practice was given under the direction of a senior registered physical therapy technician. This class of technicians could start in all the approved schools by Jan. 1, 1941. The class could finish at the schools in twenty weeks if necessary and take the 400 hours of practice in the physical therapy department of an army general hospital or continue the practice hours in the school if an emergency does not exist.

In the event of a national emergency, the time element is important. Therefore it would seem necessary to formulate definite plans now to meet any essential demand for medical services either to the civilian population or to the armed forces.

122 South Michigan Avenue.

COMMITTEE TO COORDINATE MINNESOTA'S DEFENSE EFFORTS

An all-university committee appointed to coordinate the efforts of the University of Minnesota to cooperate in national defense has been appointed with Dr. Harold S. Diehl, dean of medical sciences at the university, as chairman. The defense efforts of the university at present include (1) organization of the United States General Hospital No. 26, (2) training men in the naval R. O. T. C.; (3) participating in the civil aeronautics authority flight program, (4) pushing two medical school research projects, one of which is concentrated on surgery and the other on human fatigue and (5) the lending of Elvin B. Stakman, Ph.D., to a government expedition to South America to study the possibility of expanding rubber production. The University of Minnesota also is one of four universities selected to assist in studies of the impact of the preparedness and defense program on business.

Organization Section

OFFICIAL NOTES

ADDRESSES BY OFFICIAL STAFF

DR. PAUL C. BARTON:

September 11—Meeting of the Second District of the Medical Society of Wisconsin, Lake Geneva, Wis.

DR. W. W. BAUER:

October 5.—La Porte County Public School Teachers Meeting, La Porte, Ind.

DR. PAUL A. TESCHNER:

September 30—Chicago Tuberculosis Institute at University Clinics, Chicago.

October 3—Interprofessional Men's Institute, St. Paul.

October 4—Mississippi Valley Conference on Tuberculosis, St. Paul.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. J. Res. 286, previously passed by the Senate and the House with amendments, has been reported out of conference and the report of the conferees adopted by the Senate and the House, authorizing the President, during the period ending June 30, 1942, to order into active military service, in the Western Hemisphere and in the territories and possessions of the United States, for a period of one year, retired personnel of the Regular Army and any or all members and units of any or all reserve components of the Army. S. 4203 has been reported to the Senate with amendments, providing that in the discretion of the President retired officers, warrant officers, nurses and enlisted men of the Regular Army may be employed or assigned to active duty, with their consent in time of peace but with or without their consent in time of war. S. 4224 has been reported to the Senate with amendment, providing that in time of war or during an emergency declared by the President or by Congress the Secretary of War may, in his discretion, dispense with any part of the examination for promotion in the Regular Army of officers of the Medical, Dental and Veterinary Corps, except the physical examination. S. 4245 has been reported to the Senate without amendment, proposing to authorize the Secretary of the Navy to establish naval hospitals at the naval air stations at Jacksonville, Fla., and San Juan, Puerto Rico; the submarine base, Coco Solo, Canal Zone; the naval station, Guantanamo Bay, Cuba, and the Marine Barracks, Quantico, Va. H. R. 8613 has passed the House without amendment, providing that any person who served as a member of the Army Nurse Corps or of the Navy Nurse Corps during the World War and continuously thereafter until May 13, 1926, and who was, prior to June 20, 1930, separated from said corps by reason of physical disability incurred in line of duty, shall, on her application therefor, be entitled to be placed on the retired list of the Nurse Corps of which she was a member, her retired pay becoming effective on the date of receipt by the Secretary of War or the Secretary of the Navy, as the case may be, of such application or the date of enactment of this bill, whichever is later.

Bills Introduced.—H. R. 10382, introduced by Representative Boykin, Alabama, proposes to grant permanent total disability rating to World War veterans suffering service connected tuberculosis disability if such disease remains active after two years' hospitalization and is not expected to become arrested by further hospitalization. H. R. 10384, introduced by Representative McCormack, Massachusetts, proposes to amend the Social Security Act and the Internal Revenue Code so as to extend old age and survivor insurance benefits and unemployment benefits to, among others, employees of nonprofit religious, charitable, scientific, educational and anticruelty organizations, except ordained ministers and members of religious orders performing their duties in such orders and student nurses and interns.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Health Department Headquarters Transferred to Los Angeles.—Newspapers reported, July 17, that the headquarters of the state department of health had been transferred to Los Angeles. Alterations have been approved for the Los Angeles office to accommodate Dr. Bertram P. Brown, Los Angeles, recently appointed director of the department, and his staff, it was stated.

Medical School Center in Pediatric and Obstetric Program.—The University of California Medical School, San Francisco, will be the center of all postgraduate education in pediatrics and obstetrics in a long term educational program planned by six cooperating states: California, Nevada, Utah, Idaho, New Mexico and Arizona. According to the university *Clip Sheet*, the program will be financed by funds from the participating states, the U. S. Children's Bureau and the Rosenberg Foundation. Selected physicians from each state will attend refresher courses offered by the university. Transportation and tuition will be paid by the home states. In addition, a pediatric "circuit rider" will be appointed to travel through the western states for consultations with individual physicians, district medical societies and other interested groups on problems involving the care of young children. Dr. Amos U. Christie, associate professor of pediatrics at the university, will direct the program.

CONNECTICUT

Personal.—Dr. Benjamin G. Horning has resigned as health officer of Hartford to become associate field director of the American Public Health Association for the United States and Canada, according to the state medical journal. Dr. Horning has been health officer of Hartford for four years. He graduated at Harvard Medical School, Boston, in 1928.—Dr. Ross G. Harrison, Sterling professor of biology emeritus, Yale University School of Medicine, New Haven, received the honorary degree of doctor of science from Columbia University at the recent commencement.

Sixteenth Annual Clinical Congress.—The Connecticut State Medical Society will hold its sixteenth clinical congress in New Haven, September 17-19. The following will participate:

- Dr. Elliott P. Joslin, Boston, Newer Developments in the Treatment of Diabetes.
- Dr. Nicholson J. Eastman, Baltimore, Complications of Pregnancy.
- Dr. Herrman L. Blumgart, Boston, Treatment of Coronary Artery Diseases.
- Dr. Grover F. Powers, New Haven, Chemotherapy of Streptococcus Empyema.
- Dr. Howard W. Brayton, Hartford, Use of Vitamin K in Hemorrhagic Diseases of the Newborn.
- Dr. James D. Trask, New Haven, Diagnosis of Pneumococcus Types from Nasal Washings.
- Dr. Eugen Kahn, New Haven, Contraindications to Marriage from the Psychiatric Viewpoint.
- Dr. James Flexner, New York, What We Can Learn from Gastroscopy.
- Dr. Wilder G. Penfield, Montreal, The Epilepsies.
- Dr. Martin Henry Dawson, New York, Treatment of Chronic Arthritis with Special Reference to the Use of Gold Salt.
- Dr. Alvan L. Barach, New York, Gas Inhalation Therapy.
- Dr. Frank R. Ober, Boston, Significance of Low Back Pain.
- Dr. Clarence D. Selby, Detroit, An Approach to the Problems of Adult Life Through Industry.

DELAWARE

State Medical Meeting September 9-11.—The Medical Society of Delaware will hold its one hundred and fifty-first annual session at the Henlopen Hotel, Rehoboth Beach, September 9-11, under the presidency of Dr. Bruce Barnes, Seaford. Included among the speakers are:

- Dr. Emil Novak, Baltimore, Some Endocrine Aspects of Gynecology.
- Dr. James E. Marvel, Laurel, Otitis Media.
- Dr. John A. Kelmer, Philadelphia, The Present Status of Vaccination Against Disease.
- Dr. George C. Griffith, Philadelphia, The Significance of Precordial Pain.
- Dr. Ernest L. Stebbins, Albany, N. Y., Streptococcal Infections.
- Dr. Edward Weiss, Philadelphia, Renal Aspects of Hypertension.
- Dr. Carl H. Davis, Wilmington, Complicated Labor.
- Dr. Joseph B. Wolfe, Philadelphia, Atheromatous Cardiovascular Disease.

GEORGIA

Personal.—Dr. Harold W. Long, Milledgeville, has been appointed director of the crippled children's division of the state department of public welfare. He is a graduate of the University of Georgia School of Medicine, Augusta, class of 1936.

Anatomist Accepts Fellowship at North Carolina.—Dr. Charles W. Harwell, since 1921 a member of the staff of Emory University School of Medicine and since 1923 assistant professor of micro-anatomy and neuro-anatomy, has resigned to accept a fellowship in public health at the University of North Carolina. Dr. Harwell graduated at Emory in 1921.

District Meeting.—The First District Medical Society was addressed in Savannah, July 17, among others, by:

- Dr. Patrick H. Smith, Savannah, Regional Anesthesia.
- Dr. Louis Fielding Lanier, Sylvania, Coronary Thrombosis with Diabetes.
- Dr. Elton S. Osborne, Savannah, Psychoanalysis and Medical Psychology.
- Dr. Lee Howard, Savannah, The Practical Importance of Certain Drug Blood Levels.
- Dr. Henry T. Compton, Savannah, The Septic Hip.

Dr. Job C. Patterson, Culbert, president of the state medical association, also addressed the meeting.

IDAHO

Bubonic Plague.—*Public Health Reports* announces the diagnosis of bubonic plague in a boy aged 13 years at Emmett, Gem County. The diagnosis was made by Surg. Le Grand B. Byington of the Public Health Service Plague Suppressive Measures Laboratory in San Francisco.

Society News.—The state medical association sponsored a lecture tour which included a dinner meeting with the Pocatello Medical Society, July 13; South Side Medical Society in Twin Falls, July 14, and an evening meeting with the Southwestern Medical Society at Boise, July 15. The speakers were Drs. Constantine F. Kemper, associate professor of medicine, University of Colorado School of Medicine, Denver, whose subject was "Newer Procedures in Management of Ductless Gland Diseases," and Kenneth D. A. Allen, Denver, "Carcinoma of the Cervix."

ILLINOIS

Physicians Honored.—A dinner was held in Mason City recently, honoring Dr. Chauncey W. Cargill on his completion of fifty years in the practice of medicine. The dinner was given under the auspices of the Mason City Rotary Club and the Mason County Medical Society. A medal was presented to Dr. Cargill by the Illinois State Medical Society. A similar honor marked the fiftieth anniversary in medical practice of Dr. Jasper M. Adams. Dr. Adams has practiced thirty-seven years in Canton.

CHICAGO

Personal.—Dr. Gustavus M. Blech recently received the military surgeon's medal from the Mexican Ministry of National Defense in recognition of his publications on war surgery and medicomilitary problems.

Memorial to Dr. Fantus.—Plans are under way to place a plaque in the new outpatient clinic building at Cook County Hospital in honor of the late Dr. Bernard Fantus, for whom the clinic building was named. Those who wish to contribute to this memorial should send their checks to the Bernard Fantus Memorial Fund, care of Elizabeth M. Adles, department of therapeutics, Cook County Hospital, 1825 West Harrison Street. The new outpatient clinics of the hospital group were dedicated, April 19, to the memory of Dr. Fantus, director of therapeutics at the hospital and creator of the "blood bank" for quick transfusions.

KENTUCKY

State Medical Meeting at Lexington.—The annual meeting of the Kentucky State Medical Association will be held in Lexington, September 16-19, under the presidency of Dr. Austin Bell, Hopkinsville. Dr. Nathan E. Van Etten, New York, President of the American Medical Association, will deliver an address Tuesday evening, September 17, on "An American Health Program," and Dr. Arthur W. Allen, Boston, will speak on "Surgical Consideration of the Gallbladder and Bile Ducts." Wednesday evening at the annual dinner Dr. Bell will deliver his presidential address and Dr. Tinsley R. Harrison, Nashville, Tenn., will speak on "Management of Patients with Acute Myocardial Infarction." The annual oration in surgery will be delivered by Dr. Allen E. Grimes, Lexington,

on "Lung Abscess" and the oration in medicine by Dr. Oscar O. Miller, Louisville, on "The Evolution of Our Knowledge of Tuberculosis." Among other speakers will be:

- Dr. James R. Hendon, Louisville, An Evaluation of the Present Status of Male Hormone Therapy.
- Dr. Thomas J. Marshall, Paducah, Vitamins—Their Use in Children.
- Dr. Fred W. Rankin, Lexington, Indication of Surgery and Choice of Operation in Peptic Ulcers.
- Dr. Shelton Watkins, Louisville, Hoarseness, An Important Symptom.
- Dr. Joseph Gant Gaither, Hopkinsville, The Problem of Drainage Following Operation in the Bile Passages.
- Dr. Lawrence T. Minish, Frankfort, Edema—Types and Management.
- Dr. David Woolfolk Barrow, Lexington, Treatment of Appendical Peritonitis.

MAINE

Memorial Clinic.—A medical and surgical clinic, formed by physicians of Gardiner and Richmond, was opened in Gardiner, July 6, and will work in cooperation with the Gardiner General Hospital with access to all of the hospital's laboratory facilities. The new clinic is named for the late Dr. Ralph D. Simons, who practiced in Gardiner for twenty-five years.

MICHIGAN

State Medical Meeting in Detroit.—The seventy-fifth annual session of the Michigan State Medical Society will be held at the Book-Cadillac Hotel, Detroit, September 25-27, under the presidency of Dr. Burton R. Corbus, Grand Rapids. The program includes sectional meetings and seven general assemblies. Among the out of state speakers will be:

- Dr. Wallace M. Yater, Washington, D. C., Surgery of the Heart and the Heart in Surgery.
- Dr. Hugh Hampton Young, Baltimore, Medical and Surgical Aspects of Diseases of the Prostate.
- Dr. Arthur R. Elliott, Chicago, Arterial Hypertension: Forty Years in Retrospect.
- Dr. Julian Deryl Hart, Durham, N. C., Self-Inflicted Injuries.
- Dr. Paul A. O'Leary, Rochester, Minn., Modern Trend in the Treatment of Syphilis.
- Dr. John H. Musser, New Orleans, Vitamin and Mineral Requirements in Pregnancy and the Puerperium.
- Dr. Ralph M. Waters, Madison, Wis., Methods of Resuscitation.
- Dr. Charles F. McKlann, Boston, Cyanosis of the New Born.
- Dr. Richard N. Pierson, New York, Planned Parenthood: Its Contribution to National Preparedness.
- Dr. William G. Birch, Saulte Ste. Marie, Postpartum Sterilization.
- Dr. Jacob P. Greenhill, Chicago, The Three Newest Hormones in Gynecology.
- Dr. Walter Ivan Lillie, Philadelphia, Retinal Changes Associated with Arterial Hypertension.
- Dr. Hans Brunner, Chicago, Indications for Simple and Radical Mastoidectomy.
- Dr. Joseph Stokes Jr., Philadelphia, Prophylaxis to Measles.
- Dr. Nicholson J. Eastman, Baltimore, A Study of Alpha-Loheline, Metrazol and Coramine in Experimental Anoxia.
- Dr. John G. Downing, Boston, Industrial Aspects of Dermatitis and Eczema.
- Dr. Thomas T. Mackie, New York, Medical and Surgical Significance of Avitaminosis.
- Dr. Edward William Alton Ochsner, New Orleans, Complications of Appendicitis.
- Dr. Henry C. Sweany, Chicago, The Primary Tuberculous Infection in Adults (sponsored by Michigan Tuberculosis Association).
- Dr. Paul A. Neal, Washington, D. C., Responsibility of the Medical Profession in Industrial Hygiene (sponsored by Michigan Department of Health).
- Dr. Samuel A. Cosgrove, Jersey City, N. J., Hospital Organization and Staff Work as Factors in Maternal Health (sponsored by W. K. Kellogg Foundation).
- Dr. Helen Flanders Dunbar, New York, Psychosomatic Aspects of Illness (sponsored by McGregor Health Foundation).
- Dr. Luther Emmett Holt Jr., Baltimore, Observations on Deficiencies of the Vitamin B Group (sponsored by Children's Fund of Michigan).
- Dr. Ambrose L. Lockwood, Toronto, Surgical Dyspepsias.
- Dr. Chevalier L. Jackson, Philadelphia, Broncho-Esophagology in Relation to General Practice.
- Dr. John D. Camp, Rochester, Minn., Tumors of the Scalp and Skull and Their Significance as Revealed by Roentgenograms.
- Dr. Reginald Fitz, Boston, Changing Picture of Diabetes.

Dwight Anderson, LL.B., New York, will address the county secretaries' conference Wednesday noon, September 25, on "Good Public Relations by the Individual Practitioner of Medicine." The program also includes symposiums on pre-operative and postoperative treatment in surgery and on anoxia. Dr. Rufus I. Cole, Mount Kisco, N. Y., will deliver the Andrew P. Biddle Oration at a public meeting, Wednesday evening. His subject will be "Role of Medical Societies in Medical Progress." The Biddle Oration Scroll will be presented to Dr. Cole following his lecture.

The Michigan branch of the American Medical Women's Association will meet at the Women's City Club, Detroit, September 24. A dinner will be held to honor Dr. Martha L. Longstreet, Saginaw, and speakers will be Drs. Ruth Herrick, Grand Rapids, and Mary Ruth McGuire, Detroit, whose subjects will be, respectively, "When to Refer Dermatoses" and "Obstetrical Observations."

MINNESOTA

Society News.—Dr. Morris Fishbein, Chicago, Editor of *THE JOURNAL*, gave a special lecture at the Mayo Foundation House, Rochester, July 26, on "Problems Involving Medical Preparedness."

University News.—Lemen J. Wells, Ph.D., assistant professor of anatomy, University of Missouri School of Medicine, Columbia, since 1938, has been appointed associate professor of medicine at the University of Minnesota Medical School, Minneapolis, according to *Minnesota Medicine*.

Personal.—Dr. Alfred M. Ridgway, Annandale, celebrated his fiftieth anniversary in the practice of medicine July 14. At a gathering held to honor him, the speakers included Drs. Berton J. Branton, Willmar, president-elect of the Minnesota State Medical Association; George E. Sherwood, Kimball, and Archibald H. Beard, Minneapolis.

MISSOURI

Jackson County Health Forum.—The program for the 1940-1941 Jackson County Health Forum, sponsored by the auxiliaries of all the accredited hospitals of Jackson County, will be presented in Kansas City as follows:

- Dr. Warren T. Vaughan, Richmond, Va., September 18, Allergy, the Mystery Disease.
- Dr. Anton J. Carlson, Chicago, October 16, The Nature of Aging and the Chimera of Rejuvenation.
- Dr. Walter C. Alvarez, Rochester, Minn., November 20, What's the Matter with the Patient Who Is Tired All the Time?
- Dr. Andrew C. Ivy, Chicago, December 18, The Effects of Narcotics and Alcohol on the Human Body: Facts, Not Opinion.
- Ernest R. Groves, B.D., Chapel Hill, N. C., Jan. 15, 1941, Marriage and Sex Education.
- Dr. Henry H. Turner, Oklahoma City, February 19, Glandular Mechanism of the Body.
- Dr. Bernard L. Wyatt, Tucson, Ariz., March 19, Arthritis—the Great Responsibility and Opportunity.
- Dr. Morris Fishbein, Chicago, Editor of *THE JOURNAL*, April 16, Your Heart and Your Blood Pressure.
- Dr. William A. O'Brien, Minneapolis, May 21, Medicine Meets Middle Age Needs.

NEW YORK

Gastro-Enteritis from Custard Pastries.—Fifteen cases of gastro-enteritis in four households in Nassau County were recently traced to custard pastries, all obtained from one bakery. *Staphylococcus aureus* was obtained from samples of the pastries and, although the bakery personnel had had no recent illness, insanitary practices and conditions were found, according to *Health News*.

Industrial Conference.—The 1940 medical conference of the General Motors Corporation was held in Buffalo recently. Speakers included Drs. George O. Gundersen, Lansing, Mich., on "Iontophoresis in the Treatment of Fungous Infections of the Skin"; Robert A. Kehoe, Cincinnati, "Control of Occupational Exposures to Lead"; Lydia G. Giberson, New York, "Technic of Listening to Worried Employees," and Arthur G. Cranch, New York, "Health Aspects of the Oxy-Acetylene Process."

Saratoga Springs Advisory Committee.—The Saratoga Springs Authority recently entertained the statewide medical advisory committee at a meeting at the spa with papers by the medical staff. Guest speakers were Dr. Russell L. Cecil, New York, on arthritis and Edward H. L. Corwin, Ph.D., New York, on convalescence. Appointment of this committee was authorized by the law that created the Saratoga Springs Authority and forty-one officers of state, district and county medical societies have accepted appointment, it was announced. Subsequent regular meetings are to be arranged by an executive committee elected at this meeting.

New York City

Books on Military Medicine.—An exhibit of books on historical aspects of military medicine is on view at the New York Academy of Medicine. The display begins with one of the earliest records of gunshot wounds and continues chronologically up to an account of gas warfare published in 1940, according to *New York Medical Week*. Rare books in the academy's library are included. The exhibit was arranged by Dr. Thomas Archibald Malloch, the librarian, and the library staff as part of the medical profession's preparedness plan.

Annual Graduate Fortnight.—The New York Academy of Medicine will present its annual Graduate Fortnight, October 14-25. Clinics will be held each afternoon at two hospitals and evening sessions will be at the academy building. At the first general session Dr. Eli K. Marshall Jr., Baltimore, will deliver the Ludwig Kast Lecture on "Experimental Basis of Chemotherapy in the Treatment of Bacterial Infections" and Dr. Perrin H. Long, Baltimore, the Wesley M. Carpenter

Lecture on "Clinical Bacterial-Chemotherapy; Results Obtained and Dangers Encountered." Speakers at other evening sessions will include:

- Dr. Emanuel Libman, General Consideration of Bacterial Infections.
- Dr. Frank L. Meleney, Prevention and Treatment of Infection in Wounds, Both Operative and Accidental.
- Dr. Hobart A. Reimann, Philadelphia, Pneumococcal and Virus Pneumonia.
- Dr. Robert M. Lewis, New Haven, Conn., Gonococcal Infections in the Female.
- Dr. Percy S. Pelouze, Philadelphia, Gonococcal Infections in the Male.
- Dr. William Thalheimer, Treatment of Infections by Methods Other Than Chemotherapy.
- Dr. Thomas M. Rivers, Virus Infections.
- Dr. John R. Paul, New Haven, Conn., Acute Poliomyelitis.
- Dr. Walter M. Simpson, Dayton, Undulant Fever.
- Dr. George Blumer, New Haven, Rickettsial Diseases.
- Dr. Tracy J. Putnam, Newer Conceptions of Postinfectious and Related Forms of Encephalitis.

There will also be four morning panel discussions, with chairmen and subjects as follows: Drs. Long, chemotherapy in infections; Frederic W. Bancroft, osteomyelitis and bacterial infections of joints; Thomas T. Mackie, relation of vitamins to infection, and Alexander T. Martin, infections in children.

NORTH CAROLINA

Personal.—Dr. William P. Holt, Erwin, was honored by the Harnett County Medical Society at a dinner August 5. Dr. Holt is 70 years old and has practiced medicine forty-five years. He was graduated from Jefferson Medical College of Philadelphia in 1895.

New Building for Charlotte Presbyterian Hospital.—A new building with accommodations for 160 beds and twenty-five bassinets was opened by the Presbyterian Hospital, Charlotte, with a reception to the public July 18. The new plant was built in front of the old building, formerly a college, at a cost of about \$600,000. The funds were raised through large gifts from the Duke Endowment, large and small private gifts, including donations by the Presbyterian churches of the city and Mecklenburg County. The hospital was established in 1898 and has previously expanded its capacity by moving several times. The college property, which has ten acres of ground, was purchased in 1917 and remodeled to provide 100 beds and ten bassinets. The Rev. C. C. Beam is the superintendent, Dr. Oren Moore is president of the medical staff and Dr. William Marvin Scruggs, chairman of the medical advisory committee.

PENNSYLVANIA

Personal.—Dr. Ralph Emerson Buckley, Hazleton, was elected commander of the Pennsylvania department of the Military Order of the Purple Heart at the annual convention recently.—Dr. John B. Carrell, Hatboro, who recently celebrated his eighty-ninth birthday, is compiling a historical scrapbook of the Bucks County Medical Society.—Dr. Effie C. Ireland of the staff of Laurelton State Village, Laurelton, has been appointed superintendent to succeed Dr. Mary Moore Wolfe, who had been superintendent of the institution since its opening in 1919.

Philadelphia

Dr. Craighill Appointed Acting Dean.—Dr. Margaret D. Craighill, Greenwich, Conn., has been appointed acting dean of the Woman's Medical College of Pennsylvania to fill the vacancy caused by the retirement of Dr. Martha Tracy. Dr. Craighill graduated from Johns Hopkins University School of Medicine, Baltimore, in 1924 and was assistant resident in gynecology at Johns Hopkins Hospital from 1926 to 1928. Since 1928 she has been in private practice in Greenwich.

SOUTH CAROLINA

Annual Piedmont Assembly.—The annual Piedmont Postgraduate Clinical Assembly will be held at the Anderson County Hospital, Anderson, September 17-19. The program includes the following addresses:

- Dr. Jack C. Norris, Atlanta, Ga., Technical and Chemical Importance of the Erythrocyte Sedimentation Rates.
- Archie Black, Ph.D., Squibb Institute for Medical Research, New Brunswick, N. J., Recent Work in the Field of Vitamin Therapy.
- Dr. Everett L. Bishop, Atlanta, The Melanomas.
- Lieut. Col. James E. Aeb, Army Medical Museum, Washington, D. C., Bone Pathology.
- Dr. James J. Clark, Atlanta, X-Ray in the Treatment of Infections.
- Dr. Robert A. Ross, Durham, N. C., Sex Endocrine Therapy and Pelvic Surgery.

In cooperation with the South Carolina division of the Southeastern Surgical Congress, the assembly will present a symposium on fractures by Drs. William A. Boyd, Columbia; Joseph Warren White and Charles O. Bates, Greenville; Carroll J. Scurry, Greenwood; Lowell H. Coleman, Spartanburg;

Frank A. Hoshall, Charleston; Austin T. Moore, Columbia, and Edward T. Kelley, Kingstree. Dr. Le Grand Guerry, Columbia, will introduce the symposium with "A Potpourri of Surgical Impressions." At an evening dinner Dr. William L. Pressly, Due West, president of the South Carolina Medical Association, will discuss "Military Preparedness and the Physician." Dr. Edgar A. Hines, Seneca, is president of the assembly.

TENNESSEE

Surgical Meeting.—The Tennessee division of the Southeastern Surgical Congress will meet in Shelbyville, September 17, with the Bedford County Medical Society as host. Among the speakers will be Drs. Edgar G. Ballenger, Atlanta, Ga., on "Hematuria—Pyuria"; Irvin Abell, Louisville, Ky., "Problems of the Mammary Glands," and Troy P. Bagwell, Knoxville, "Management of the More Common Types of Fractures."

GENERAL

New Ruling on Case Records for Board Examinations.—The American Board of Obstetrics and Gynecology at its recent annual meeting at Atlantic City adopted a ruling that case records submitted by candidates must be of patients treated within four years prior to the date of the candidate's application. In addition, the ruling stipulated that the number of cases taken from the candidate's residency service should not be more than half (twenty-five) of the total number (fifty) of cases required. Applications for the next examination and review of case histories (Part I) for group B candidates, which will be held in various cities of the United States and Canada on Saturday, Jan. 4, 1941, must be on file in the office of the secretary not later than October 5, the board announced. For further information and application blanks, address Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh.

Outbreak of Poliomyelitis in Indiana.—One hundred and ninety-four cases of infantile paralysis were reported in Indiana for the four weeks ended August 24, newspapers reported. Twenty deaths have been reported in the state since June 1. Most of the cases, 10 per cent of which are in adults, have been in the northern half of the state. Two cases were recorded in June, seventeen in July and for the consecutive four weeks in August, fifteen, forty-one, fifty-eight and seventy-nine. Reports from counties showed fifty-one cases and six deaths in St. Joseph, forty-one in Elkhart, seventeen in Marshall, fourteen in Marion and ten in Fayette. In St. Joseph County the opening of all schools has been postponed two weeks until September 16. Children are not permitted to attend theaters, picnics are not permitted in parks and other gatherings are being discouraged. School openings in the city of La Porte and La Porte County have been postponed from September 3 to September 9. Six high schools in the eastern division of the Northern Indiana High School Conference have ordered suspension of football practice and have canceled the first two games of the football schedule: Washington, Central, Riley and John Adams in South Bend; Central in Mishawaka, and the high school in Goshen. Every effort is being directed by the state health department and cooperating agencies toward controlling the outbreak, including educational activities for parents and practicing physicians. The state maintains hospital service for acute and convalescing cases of poliomyelitis at the Indiana University Medical Center, Indianapolis. The crippled children division of the state department of public welfare has funds available to furnish medical consultation to physicians any place in the state for their patients in the acute stages. This division also has six orthopedic nurses who are available to assist physicians in the proper splinting of paralyzed muscle groups in the acute stage of the disease. The National Foundation for Infantile Paralysis has placed its equipment and facilities at the disposal of the state department of health, including iron lungs, splints and frames.—A release from the state department of health of Iowa indicates that seventy-three cases of poliomyelitis were reported for the week ended August 24, as compared with one for the corresponding week last year.—Newspaper clippings report an increasing number of cases in northern Michigan. Between May 15 and August 22 sixty cases with nine deaths were reported from seven upper peninsula counties.

CORRECTION

Pan American Sanitary Conference.—In a news item under Latin America in THE JOURNAL, August 17, page 545, it was stated that the Pan American Conference of Directors of Health would meet in Rio de Janeiro in 1942. This should have been the Pan American Sanitary Conference.

Aug. 1, 1940.

Special Surgical Centers for War Casualties

In December last the Ministry of Health announced that arrangements had been made for establishing special centers for the treatment of faciomaxillary, head and chest injuries and orthopedic cases of the war. The medical superintendents of war hospitals were told that there should be no hesitation in transferring suitable cases to these centers, as success depended on casualties reaching centers where specialist skill and equipment were available at the earliest possible time. The types of cases to be sent to orthopedic centers were fractures, deformities of the limbs and spine, diseases and derangements of joints, including the spine, and injuries of the peripheral nerves. Now that a considerable number of casualties are being admitted to the war hospitals, the ministry has again drawn attention to the need for transferring cases to the special centers when this can be done without risk to the patient. Early transfer is enjoined in all types of cases but particularly in faciomaxillary cases and cases in which plastic surgery may be needed. If advice is required as to the line of treatment to be adopted or if there is any doubt as to the desirability of transferring the case, the assistance of the appropriate consultant adviser should be sought. There are now in England ten special surgical centers for the treatment of faciomaxillary injuries, six for the treatment of head injuries, nine for chest injuries and eighteen for orthopedic cases.

Body Armor in War

The use of body armor in war continues to be discussed. The important discussion at the Section of Surgery of the Royal Society of Medicine was reported previously. The suggestions were not confined to body armor but concerned also the strengthening of certain parts of aircraft and other machines. For this purpose compressed fiber and materials such as bakelite, which are very light yet capable of withstanding shrapnel, are suitable. Experiments were made in the last war with body armor. Breastplates were put on the market by several firms and were occasionally issued on trial. They were also sometimes found in captured German machine gun positions. The chief argument against them was their weight. It was thought that some of them might result only in the expansion of the bullet and thus increase the severity of the wound. But since then progress has been made in producing light metals of great tensile strength.

In modern war many men are killed by small missiles which enter the chest and pierce a blood vessel or the heart. Often there is no great velocity behind these missiles. There are many cases of bullets or splinters being stopped by a cigaret case or a little flask carried in the breast pocket. It should not be impracticable to provide certain troops, such as machine gun detachments, with some protection on the these lines. The shrapnel helmet, now adopted by all armies, has proved invaluable but does not protect the eyes from missiles not coming from above. For this purpose a duralumin visor has been suggested. Though the whole energies of the country are as far as possible diverted to war, nothing so far is known of the production of body armor.

The International Standards for Antitoxin and Tuberculin

The international standards for serums and bacteriologic products are held on behalf of the Health Organisation of the League of Nations by the State Serum Institute, Copenhagen, which

has furnished samples to institutions and research workers in different countries. As the war has interrupted the supply, the league has requested the Medical Research Council in London to allow samples of the British standards for these products held by it to be furnished to those who have hitherto received the international standards from Copenhagen. The Medical Research Council has agreed to do this and so prevent the complete interruption of the service. The British standards are either part of the same materials as those kept at Copenhagen or have been repeatedly tested by the British and Danish institutes to ensure that the units determined in terms of the British standards are exactly equivalent to the international units. The following are the standards available: (1) Identical in material with the international standards: staphylococcus antitoxin, gas gangrene antitoxins (perfringens, *Vibrio septique*, oedematis, histolyticus), antidyentery serum (Shiga), antipneumococcus serum (types I and II), old tuberculin. (2) Different in material but with identity of the unit indication confirmed twice a year at Copenhagen and London: diphtheria antitoxin, tetanus antitoxin. The British can also supply a standard solution of diphtheria antitoxin for the flocculation test. The stocks are adequate to meet all demands except for antipneumococcus serums and it is therefore requested that demands for these be restricted to essential needs. It is also requested that, in order to conserve these standards, laboratories will cooperate by establishing local standards the potency of which has been determined by comparative tests.

The Treatment of War Wounds

The Medical Research Council has appointed a committee, which includes representatives of the fighting services and the emergency service established for the treatment of war casualties under the Ministry of Health, to advise on the application of the results of research to the treatment of wounds. The committee consists mostly of eminent surgeons, some of whom hold military or naval rank attained for service in the last war: Sir Cuthbert Wallace (chairman), Mr. E. Rock Carling, Mr. C. H. S. Frankau, Prof. F. R. Fraser, Prof. G. E. Gask, Surgeon Rear Admiral G. Gordon Taylor, Col. Sir Charles Gordon-Watson, Major General H. Marrian Perry, Prof. R. S. Pilcher and Prof. J. Paterson Ross. There are two bacteriologists: Sir John Ledingham, F.R.S., and Prof. W. W. C. Topley.

The Highest Marriage Rate on Record

One result of the war is to produce the highest marriage rate on record. In 1939 it was 21.1 per thousand of population against 17.6, 17.5 and 15.8 in the preceding years backward. The connection with the war is shown by the fact that the increase took place in the second half of the year. The reason is that most of our young men are in the fighting forces and that their wives and children are entitled to allowances, including pensions in case of death.

Sir George Berry

Sir George Berry, a leading ophthalmologist, has died in his eighty-seventh year. Educated at Edinburgh, he studied ophthalmology for some years in various European hospitals. In Copenhagen he worked with his uncle, Prof. Hansen Grut, a distinguished ophthalmologist. While still comparatively young, Berry was regarded as an authority both on the European continent and in America. He produced a textbook, "Diseases of the Eye," which had a great reputation not only as an exhaustive treatise but as embodying many original observations and ideas. Two other works, "Subjective Symptoms in Eye Disease" and "Ophthalmoscopic Diagnosis," were also widely read. His remarkable knowledge of the significance of early symptoms in the early diagnosis of disease not only was valuable in diagnosis but gave great interest to his teaching of students. He served on the staff of the eye department of the Royal Infirmary,

Edinburgh, for twenty-three years. He was one of the founders of the Ophthalmological Society of the United Kingdom, of which he was president in 1909-1911. He contributed many important papers to its transactions.

BUENOS AIRES

(From Our Regular Correspondent)

Aug. 2, 1940.

Influenza in Buenos Aires

A widely prevalent infectious catarrh, generally called grip but having nothing in common with the malignant form of 1918, and which involves entire families, has been active since the beginning of July in what is the winter season of this hemisphere. Persons affected need to stay in bed for a few days. Fever as high as 103 F. is encountered, accompanied with disorders of the upper respiratory passages, less frequently with those of the gastrointestinal tract. Its virulence is attributed to the brusque climatic changes that were frequent this year. Micro-organisms such as pneumococci, Pfeiffer's bacillus and Neisseria catarrhalis, generally found on the oral and pharyngeal mucosa, are activated by severe changes of temperature. No deaths have been reported.

Bubonic Plague

The four isolated cases of plague that appeared in the northern province of Salta had no geographic relation to one another. Dr. Julio D. Outcs, head of the plague control service in Salta, ascribes these isolated cases to rodents living in the woods, in which the plague bacillus was shown to be present. At the time of the occurrence of the disease there was also a considerable infestation of rats. Prophylactic inoculation against plague was demonstrated to be ineffective. General inoculation at the time of the appearance of plague is therefore useless. There is need of a new active vaccine. Professor Sordelli, director of the bacteriologic institute in Buenos Aires, has demonstrated that immunity conferred by the plague itself is permanent.

More recently new cases involving not only bubonic but also pneumonic plague have been reported from northern Argentine provinces. These no doubt are causally to be connected with the rat invasions observed there. The national health department took immediate steps to enforce the law requiring property owners and local and provincial authorities to exterminate rats and other rodents. A commission was also appointed, which has worked out extensive plans of control.

Tuberculosis

The second national conference on tuberculosis, held recently in Cali, Colombia, adopted a number of recommendations. The high infectiousness in childhood makes social prophylaxis imperative. Since, according to law, tuberculosis is considered an occupational disease, proof of infection must be submitted. It was pointed out that institutions for tuberculous persons within city limits do not constitute a danger to the community if appropriate hygienic regulations are carried out. Early diagnosis and treatment of tuberculosis as well as official protection of the public by eliminating the advertising and sale of medicines guaranteed to cure tuberculosis were demanded by the conference. Houses previously tenanted by tuberculous persons represent no source of infection if disinfection has been properly made. Prophylactic vaccination against tuberculosis as well as the training of school teachers in breathing exercises and in the protection of school children against tuberculosis was recommended.

In Lima, Peru, the first national conference on tuberculosis, held in April, called attention to the number of incurable cases and asked for an increase in hospital beds. The conference recommended the technical and scientific unification and control of all existing institutions under the proper service of the government. The organization of a national council for tuber-

culosis control, designed to extend social and economic aid over the whole country and to enlist the cooperation of philanthropists, was recommended. Facilities for lung surgery were asked. The conference recommended the study of compulsory insurance against tuberculosis in Peru, the establishment of university courses for special training in the field of tuberculosis and the control of quack advertising.

The Argentine League Against Tuberculosis is active. The state has permitted a lottery, which has met with popular favor. The price of a chance is 1 peso (30 cents). The proceeds will be used to equip the league's fourteen story tuberculosis institute now under construction. The sums of 500,000 pesos (about \$150,000) raised by public contributions and 1,050,000 pesos (about \$312,000) appropriated by the government have already been expended; the complete cost of construction and of equipment is estimated at 10,000,000 pesos (nearly \$3,000,000). It will contain 1,373 beds and research facilities. The immediate plans envisage a sanatorium with 482 beds costing about 4,300,000 pesos (\$1,280,000). The records of welfare stations and dispensaries indicate that eight out of every ten patients seeking consultation show progressive stages of tuberculosis. This alarming revelation has led to a change of procedure: patients are now visited in their homes and receive early treatment. Other organizations have likewise shown great interest in antituberculosis work. A cooperative organization, founded in 1924, in the department of justice and education has recently opened new consultation centers and will shortly operate a mountain sanatorium in Alta Gracia, Córdoba. This organization furnishes medicine, gives pensions to patients who must enter an institution and grants traveling expenses and financial aid to patients who must move to climatically favorable regions. Members pay a monthly fee of 50 centavos (15 cents). Members pay 20 centavos (6 cents) on the death of one of its members. The organization is now able to pay a death benefit as high as 8,000 pesos (\$2,380). The results achieved by this organization against tuberculosis have led to a project for compulsory insurance of this kind for all of the 270,000 federal employees.

Personal

Prof. Angel H. Roffo was appointed incumbent of the new chair of cancerology, established at the faculty of medicine of the University of Buenos Aires.

Marriages

EDWARD JAMES McDERMOTT BLANCHARD, New York, to Miss Mary Bowers Carter of Englewood, N. J., June 22.

KENNETH DUNHAM, St. Augustine, Fla., to Miss Mary Catherine Badgett of Richwood, W. Va., in July.

FRANCIS EDMUND SHEARER, Louisville, Ky., to Miss Hazel Broadus of Lancaster at Atlanta, Ga., June 22.

ROLAND HARRIS VAUGHAN, Edenton, N. C., to Miss Ruth Elizabeth Miller of Wilkes-Barre, Pa., June 1.

WILLIAM CAMP MATTHEWS, Davidson, N. C., to Miss Edith Mountcastle Summers of Charlotte, June 26.

ROBINSON MARSHALL TRUIT JR. to Miss Eleanor Marie MacDonald, both of Philadelphia, June 29.

THURMOND DE WITTE BOAZ JR., Shreveport, La., to Miss Margaret Davenport of Seattle, June 18.

HAL STANDISH JOHNSON, Berwind, W. Va., to Miss Ellen Reynolds of Chesterfield County, June 5.

CHARLES JULIAN RAGAN, New Orleans, to Miss June McCann of Brookhaven, Miss., June 15.

JOHN CLINTON ALLEN, North Haven, Conn., to Miss Ruth Hensel of Germantown, Pa., recently.

HAZEL JOSEPH WILLIAMS, Brownsburg, Va., to Miss Marion Louise Eugh of Richmond, May 25.

GUS ECKHARDT, Galveston, Texas, to DR. MARY ELIZABETH FATHERREE of New York, June 26.

Deaths

William Allen Pusey Ⓢ President of the American Medical Association, 1924-1925, died at his home in Chicago, August 29, aged 74. Dr. Pusey had a distinguished career as a scientist, a teacher, an author and a civic and medical leader. He was born Dec. 1, 1865, in Elizabethtown, Ky., the descendant of a Kentucky pioneer family. His father was a physician and his great-grandfather on his mother's side was Dr. John T. Hodgen of St. Louis, one of the most famous surgeons of his day and also President of the American Medical Association. Following graduation from Vanderbilt University in 1885, where he received the A.B. degree, Dr. Pusey continued his studies, receiving the master's degree in 1886 and election to Phi Beta Kappa. He then attended the University of the City of New York Medical Department, receiving the M.D., degree from that institution in 1888. For the next five years he did family practice in Kentucky and after his father's death spent considerable time in postgraduate training in New York and in Europe. In 1893 he came to Chicago to specialize in diseases of the skin. He was made professor of dermatology in the University of Illinois College of Physicians and Surgeons in 1894, holding that position until 1915, at which time he became professor emeritus.

Dr. Pusey became president of the American Dermatological Association in 1910 after having been president of the Chicago Dermatological Association for three terms. He was president of the Chicago Medical Society, 1918-1919, and president of the Institute of Medicine of Chicago, 1926-1927. In the American Medical Association, he served as a member of the House of Delegates from the Section on Dermatology and Syphilology in 1910 and in 1914, and as a delegate from the state of Illinois from 1926 to 1932. He was elected treasurer of the American Medical Association at the Los Angeles session in June 1911 and served in that capacity until the St. Louis session of 1922. He was also chairman of the Section of Dermatology in 1909. In 1923 he was elected President of the American Medical Association. His memberships in scientific organizations included the Chicago Pathological Society, the Chicago Roentgenological Society, the Japanese, Czechoslovakian, British, Viennese and Danish Dermatological societies, and the Dermatological Section of the Royal Society of London.

During the World War Dr. Pusey was attached to the Surgeon General's office as chairman of the committee for the control of venereal diseases.

In the scientific aspects of dermatology Dr. Pusey was a pioneer, particularly in the therapeutic use of the roentgen ray. In his book first published in 1903 he presented many new uses for the roentgen ray, including its application in leukemia and Hodgkin's disease, in which he was the first to employ it. His work as an educator in medical science is widely recognized; he was given the honorary degree LL.D. by the University of New Mexico in 1925, and he served as a member of the Commission on Medical Education from 1925 to 1932.

Notwithstanding his multitudinous scientific activities, Dr. Pusey devoted himself to civic duties and responsibilities. He was chairman of the Health Division of the Chicago Council of Social Agencies, a member of the Advisory Board of the Cook

County Bureau of Public Welfare and a director of the Non-Partisan Voters' League. He was also a member of the Executive Committee of the National Research Council, a member of the executive committee of A Century of Progress Exposition in Chicago and a member of its board of trustees, and a director of the Rosenwald Museum of Science and Industry.

Dr. Pusey's literary contributions were associated with the historical aspects of dermatology and syphilology and included not only innumerable articles in periodical literature but also books on "The Roentgen Rays in Therapeutics and Diagnosis" (1903), "The Principles and Practice of Dermatology" (1907), "Syphilis as a Modern Problem" (1915), "History of Dermatology" (1932), and "History of Syphilis" (1933). As a hobby, he concerned himself particularly with colonial history related to the state of Kentucky. His work "The Wilderness Road to Kentucky," published in 1921, was recognized as a classic contribution. He was also author of "A Doctor of the 1870's and 80's," published in 1931. His contributions addressed to the

public included a popular work on "The Care of the Skin and Hair" (1912) and other educational works on the venereal diseases. He had contributed to the *American Mercury*, *Good Housekeeping* and many other leading magazines.

No doubt, one of his greatest services to American medicine was the conducting of negotiations which resulted in establishment by the American Medical Association of the *Archives of Dermatology and Syphilology* in 1920. Under his editorship many a young man was introduced into proper methods of research in the literary aspects of his chosen profession and many were taught the fundamentals of good scientific literary expression. In January 1937 a special number of the *Archives of Dermatology and Syphilology* was dedicated to Dr. Pusey. The contributors included writers in every field of medical science, educators, historians and leaders in civic affairs. In recent years, even though in failing health, Dr. Pusey continued his activities for the advancement of medical science, aiding in the campaign against regimentation of medical practice exactly as he had fought previously for raising the standards of medical education.

The life of Dr. Pusey is conspicuous for his service to his specialty in medical science, to the institutions with which he was associated and to the organized medical profession. He lived a full life almost to the

moment of his passing, and the influence of his career will continue for many years to come.

Percy Moreau Ashburn Ⓢ Colonel, U. S. Army, retired Washington, D. C.; Jefferson Medical College of Philadelphia 1893; entered the army as an assistant surgeon in 1898 and was promoted through the grades to rank of colonel in 1917; retired in 1931 for disability in line of duty; returned to active duty from Jan. 1, 1932, to Aug. 15, 1932; was president of the Army Board for the Study of Tropical Diseases in the Philippine Islands, 1906-1907; served with the United States Commission to the Republic of Liberia in 1909; was detailed president of the Army Board for the Study of Tropical Diseases of the Philippine Islands and Ancon, Panama, in 1913; general inspector of the Panama Canal Health Department, 1914-1915; commander of the Medical Officers Training Corps at Fort Benjamin Harrison, Indiana, 1917; served with the American Expeditionary Forces, 1918-1919; was decorated with the Legion of Honor for services in France; commandant of the Medical Field Service School from 1920 to 1923; professor of military hygiene;

WILLIAM ALLEN PUSEY, M.D., 1865-1940

United States Military Academy, from 1923 to 1927; librarian of the Army Medical Library in Washington, D. C., from 1927 to 1932, when he retired; since 1932 superintendent of the Columbia Hospital for Women; fellow of the American College of Surgeons and the American College of Physicians; author of "Elements of Military Hygiene," 1909, and "History of the Medical Department of the United States Army," 1929; at one time on the editorial staff of the *Quarterly Cumulative Index Medicus*; aged 68; died, August 20, of carcinoma of the prostate with metastases to the lungs and pelvic bones.

Harold Douglas Singer @ Chicago, editor-in-chief of the *Archives of Neurology and Psychiatry* since 1934, died on his ranch in New Mexico, August 28, following a heat stroke. He was 65 years old. Dr. Singer was born in London, England, Jan. 7, 1875. Following his studies in the Merchant Taylors' School, he was educated in the University of London, St. Thomas's Hospital and the Royal College of Physicians, receiving the degrees of bachelor of medicine and doctor of medicine. He served as house physician in St. Thomas's Hospital, London, 1898, and as assistant superintendent of the Clinical Laboratory, 1899. Then he became resident in the National Hospital of London, 1900-1901, and assistant resident physician in St. Thomas's Hospital from 1902 to 1904. When he arrived in the United States in 1904 he became associate professor of neurology in Creighton University School of Medicine, Omaha, from 1904 to 1906, then

associate professor of psychiatry in the University of Nebraska College of Medicine, Omaha, 1906-1907. He served at the same time as assistant superintendent of the Norfolk (Neb.) State Hospital. In 1907 he came to Illinois as director of the Illinois State Psychopathic Institute, holding that position until 1920. He became state alienist in Illinois in 1917 and was at the same time special examiner for the Illinois Exemption Board, advisory consultant in neuropsychiatry to the Surgeon General of the U. S. Public Health Service and, from 1919 to 1922, advisory consultant for the U. S. Veterans Bureau. Since 1919 he had been professor of psychiatry at the University of Illinois College of Medicine.

Dr. Singer was a Fellow of the Royal Society of Medicine and the Royal College of Physicians and a member of the American Neurological Association, the American Psychiatric Association and the American Psychopathological Association. At the time of his death he was president of the American Neurological Association and president-elect of the American Psychiatric Association.

Early in his career he began contributing to various publications in his special field. He was author of the section on mental diseases in Nelson's Looseleaf System of Medicine and of the section on psychoneuroses in Tice's Looseleaf System of Medicine. He was distinguished as an educator both of the medical profession and of the public. In 1934 he became president of the American Board of Psychiatry and Neurology and was exceedingly active in the work of that organization. He served also as an expert witness in many legal cases.

For the American Medical Association he was appointed in 1930 as chairman of the Committee to Study Problems in Mental Hygiene and Hospitals and was chairman of the Section on Nervous and Mental Diseases, 1934-1935. He became a member of the editorial board of the *Archives of Neurology and Psychiatry* in 1930, succeeding Dr. Theodore Weisenburg as editor-in-chief in 1934, and he did significant work in the advancement of that publication. He had also been attending neuropsychiatrist at the Milwaukee Sanitarium since 1923 and attending neurologist at the Augustana Hospital since 1931. Dr. Singer possessed a quiet manner and pleasing personality, a scientific point of view and an integrity that never yielded to selfish influences.

HAROLD DOUGLAS SINGER, M.D.,
1875-1940

Horace Madison Hicks @ Amsterdam, N. Y.; Chicago Homeopathic Medical College, 1886; past vice president of the Medical Society of the State of New York; past president and secretary of the Medical Society of the County of Montgomery; veteran of the Spanish-American War; secretary of the Tuberculosis and Health Association of Montgomery County; at one time health officer, and president of the school board; on the staffs of the Amsterdam City and St. Mary's hospitals; aged 77; died, July 19, of coronary occlusion.

George Taylor Stewart, Johnston, R. I.; Hahnemann Medical College of Philadelphia, 1882; chief of staff and superintendent of the Metropolitan Hospital, Welfare Island, N. Y., from May 1, 1890, to Jan. 7, 1901, and superintendent from April 1, 1906, to Dec. 31, 1907; superintendent of the Bellevue Hospital, New York, from Jan. 7, 1901, to Jan. 14, 1903; superintendent, department of health, New York City, from Jan. 14, 1903, to April 1, 1906; aged 85; died, July 25 of chronic myocarditis and arteriosclerosis.

Benoni Mowry Latham, Mansfield, Mass.; Harvard Medical School, Boston, 1900; member of the Massachusetts Medical Society; for many years chairman of the school committee; served during the World War; past president of the Bristol North District Medical Society; on the courtesy staff of the Sturdy Memorial Hospital, Attleboro; aged 67; died, July 24, in a hospital at Taunton of chronic myocarditis and arteriosclerosis.

Claude Oliver Abernethy, Raleigh, N. C.; University of North Carolina School of Medicine, 1906; member of the Medical Society of the State of North Carolina; fellow of the American College of Surgeons; on the staffs of the Rex Hospital and St. Agnes Hospital; served during the World War; aged 59; died, July 21, in a hospital at Goldsboro of a fractured skull received in an automobile accident.

Filip Carolus Forsbeck @ Cincinnati; Rush Medical College, Chicago, 1926; surgeon, United States Public Health Service; formerly epidemiologist, Massachusetts State Health Department, and director, bureau of epidemiology, Michigan State Health Department; aged 40; died, July 13, at the United States Marine Hospital, Baltimore, of glioblastoma.

Harvey Park Barret @ Charlotte, N. C.; University of Louisville (Ky.) Medical Department, 1908; member of the American Association of Pathologists and Bacteriologists, the Society of American Bacteriologists and the American Society of Clinical Pathologists; aged 55; died, July 30, of coronary occlusion.

Rose Hirschler @ Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1899; professor of dermatology at her alma mater; member of the American Academy of Dermatology and Syphilology; aged 65; on the staff of the Woman's Hospital, where she died, July 26, of lymphatic leukemia.

Franklin Simeoe Gillespie @ Swarthmore, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1923; health officer of Swarthmore; physician to Swarthmore College; aged 43; died suddenly, July 27, while boating on the Northeast River at Northeast, Md., of coronary thrombosis.

Arthur James O'Leary, New York; University of the City of New York Medical Department, 1889; past president of the Bronx County Medical Society; formerly assistant sanitary superintendent of the health department in the Bronx; aged 71; died, July 27, of pulmonary tuberculosis.

William Henry Berge, Scranton, Pa.; College of Physicians and Surgeons, Baltimore, 1893; member of the Medical Society of the State of Pennsylvania; formerly coroner of Luzerne County and chairman of the board of health; aged 71; died, July 14, of coronary thrombosis.

Edward Wyker Closson @ Lambertville, N. J.; University of the City of New York Medical Department, 1885; formerly postmaster, county coroner, president of the school board and bank president; aged 78; died, July 19, of interstitial nephritis and cardiovascular sclerosis.

Harry Berger, Trenton, N. J.; New York Homeopathic Medical College and Flower Hospital, New York, 1914; member of the Medical Society of New Jersey; on the staff of the McKinley Hospital; aged 51; died, July 21, of injuries received in an automobile accident.

George J. Gannett, Syracuse, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1900; member of the Medical Society of the State of New York; aged 63; died, July 20, when the automobile in which he was driving was struck by a train.

Percival Bainbridge Glew, Dallas Center, Iowa; Drake University College of Medicine, Des Moines, 1913; member of

the Iowa State Medical Society; aged 50; died, July 8, in a hospital at Springfield, Ohio, of coronary occlusion and cerebral embolism.

John E. Fuller, Paris, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1888; member of the State Medical Association of Texas; aged 78; on the staff of the Sanitarium of Paris, where he died, July 20, of cerebral hemorrhage.

Archie Phelps Campbell, East Ellsworth, Wis.; University of Pennsylvania School of Medicine, Philadelphia, 1924; member of the State Medical Society of Wisconsin; on the staff of the City Hospital, River Falls; aged 46; died, July 15, of heart disease.

Thomas Irving Packard, Lanark, Ill.; Rush Medical College, Chicago, 1895; member of the Illinois State Medical Society; for many years president of the school board; aged 75; died, July 4, of cerebral embolism, arteriosclerosis and hypertension.

Ruth Webster Lathrop, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1891; at one time associate professor of physiology at the Temple University School of Medicine; aged 78; died, July 31, of chronic myocarditis.

Russell Walter Goebel, Oak Park, Ill.; University of Illinois College of Medicine, Chicago, 1925; member of the Illinois State Medical Society; aged 40; died, July 31, at his summer home near Wauconda of sclerosis of the liver.

Manly Lafayette Cummins, Ashford, Ala.; Medical College of Alabama, Mobile, 1906; member of the Medical Association of the State of Alabama; aged 63; died, July 28, in a hospital at Birmingham of carcinoma of the lung.

Fridolin John Otto Kraushaar, Aberdeen, S. D.; State University of Iowa College of Medicine, Iowa City, 1909; member of the South Dakota State Medical Association; aged 54; died, June 26, of coronary occlusion.

William Baum Small @ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1893; for many years on the staff of the Lankenau Hospital; aged 70; died, July 27, of intraventricular hemorrhage.

David Robinson @ Tillamook, Ore.; Harvard Medical School, Boston, 1906; secretary and past president of the Tillamook County Medical Society; county health officer; aged 66; died, July 27, of cerebral hemorrhage.

Timothy Francis Cotter, Haverhill, Mass.; Baltimore Medical College, 1906; member of the Massachusetts Medical Society; aged 57; died, July 3, in the Hale Hospital of carcinoma of the rectum with metastases.

John Bloomfield Beekman @ Bedminster, N. J.; University of the City of New York Medical Department, New York, 1882; aged 86; died, July 10, in the Overlook Hospital, Summit, following an operation on the prostate.

Chester LeRoy Goldsmith, Winchester, N. H.; Maryland Medical College, Baltimore, 1912; member of the New Hampshire Medical Society; aged 59; died, July 26, of coronary occlusion and myocarditis.

Irwin Scott Flegal, Karthaus, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1894; member of the Medical Society of the State of Pennsylvania; aged 75; died, August 28, of coronary occlusion.

Xenia Ethel Bond, Salem, W. Va.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1905; aged 69; died, July 23, in a hospital at Clarksburg.

Edgar E. Noel, Huntington, W. Va.; College of Physicians and Surgeons, Baltimore, 1884; aged 80; died, July 18, at St. Mary's Hospital of complications following a fractured hip, received in a fall.

Walter Scott Abbott Kimball, Rumford Point, Maine; Medical School of Maine, Portland, 1898; aged 68; died, May 20, of coronary sclerosis, phlebitis and transurethral resection of the prostate.

William S. Love @ Baltimore; University of Maryland School of Medicine, Baltimore, 1890; aged 73; died, May 13, in the Bon Secours Hospital of lobar pneumonia and acute nephritis.

John P. Kerrigan, Rutland, Vt.; Chicago College of Medicine and Surgery, 1915; served during the World War; aged 47; died, July 29, of coronary thrombosis and diabetes mellitus.

Hugh Arthur Johnston, Port Burwell, Ont., Canada; University of Toronto Faculty of Medicine, 1894; for many years associate coroner of Elgin County; aged 68; died, June 21,

Avery Barnes McGill, San Francisco; University of the City of New York Medical Department, New York, 1892; aged 76; died, July 17, of a self-inflicted bullet wound.

Ernest M. Rast, Cameron, S. C.; Medical College of the State of South Carolina, Charleston, 1898; formerly mayor; aged 69; died, July 5, of arteriosclerosis and uremia.

Walter Henderson, Hawarden, Sask., Canada; McGill University Faculty of Medicine, Montreal, Que., 1894; aged 74; died, May 1, in Spokane, Wash., of leukemia.

Frank William Love @ Buffalo; University of Buffalo School of Medicine, 1897; aged 70; died, July 21, of cerebral hemorrhage, arteriosclerosis and hypertension.

Edwin Morgan Ripley, Collinsville, Conn.; Eclectic Medical College of the City of New York, 1871; aged 92; died, June 5, of bronchopneumonia and arteriosclerosis.

Frank L. Blachly Sr., Moline, Ill.; College of Physicians and Surgeons, Baltimore, 1881; aged 80; died, July 27, in the Lutheran Hospital of mesenteric thrombosis.

Joseph Peter Bilodeau, Vancouver, B. C., Canada; McGill University Faculty of Medicine, Montreal, Que., Canada, 1913; aged 55; died, July 29, in Kamloops.

William Charles Mardorf @ St. Louis; St. Louis Medical College, 1888; an Affiliate Fellow of the American Medical Association; aged 73; died, May 5.

Thomas P. Matheny, Bardwell, Texas; Dallas Medical College, 1903; aged 73; died, July 9, in the Municipal Hospital, Ennis, of coronary occlusion.

Spero M. Salpas, Chicago; University of Illinois College of Medicine, Chicago, 1917; aged 55; died, May 2, of cerebral embolism and mitral insufficiency.

Charles Alexander Ault, Enterprise, Ore.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1890; aged 76; died, July 31, of uremia.

Isaac Henry Clement, Marion, Ky.; University of Tennessee Medical Department, Nashville, 1885; aged 78; died, June 18, of coronary thrombosis.

Thomas Francis Taylor, San Diego, Calif.; Bellevue Hospital Medical College, New York, 1880; aged 83; died, May 21, of mesenteric thrombosis.

Charles Frederick Dorsey, Innisfail, Alta., Canada; University of Toronto Faculty of Medicine, 1908; aged 55; died, June 30, of heart disease.

Daniel Harris Baker, Gadsden, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1882; aged 79; died, July 29, of myocarditis.

William Frederick Edwards, Airdrie, Alta., Canada; McGill University Faculty of Medicine, Montreal, Que., 1907; aged 60; died, June 22.

Willis Pomeroy Polhemus, San Diego, Calif.; University of Michigan Homeopathic Medical School, Ann Arbor, 1881; aged 84; died, May 1.

Hugh Burns Hay, Chipman, N. B., Canada; University of the City of New York Medical Department, New York, 1887; aged 81; died, July 16.

Roderick Donald Dewar, Melbourne, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1908; aged 58; died, May 18.

Arthur Wellesley Allingham, Broadview, Sask., Canada; Trinity Medical College, Toronto, 1891; formerly mayor; aged 75; died, May 12.

Nathan E. Lawson, Oklahoma City; Hospital College of Medicine, Louisville, Ky., 1898; aged 66; died, May 7, of myocarditis.

Mary Cochran McIntyre, Roxbury, Conn.; University of Glasgow Medical Faculty, Scotland, 1909; aged 55; died, May 12.

John James McPherson, Castor, Alta., Canada; Queen's University Faculty of Medicine, Kingston, Ont., 1909; died, May 11.

Gordon Lemon McFarlane, Carbon, Alta., Canada; University of Toronto Faculty of Medicine, 1911; aged 50; died in May.

Joseph Lawrence Bettag, Kimball, S. D.; Marquette University School of Medicine, Milwaukee, 1924; aged 49; died, May 9.

Susan L. Halverson Lamb, San Francisco; State University of Iowa College of Medicine, Iowa City, 1885; aged 79; died, May 4.

Bureau of Investigation

ROBERT FAUDREE—MEDICAL IMPOSTOR

Charlatan Finds California Climate Unhealthy

The California State Board of Medical Examiners, under the direction of the secretary, Charles B. Pinkham, M.D., has for years maintained an extensive and efficient group of investigators. These special agents have long been a thorn in the side of impostors, irregulars and those who exceed their legal rights in practicing the healing arts in the state of California.

On June 28, 1940, T. P. Hunter, a special agent for the board, had occasion to investigate one Robert Gordon Faudree, who appears to have used at that time another name, Gilbert Gordon Faudree. He had appeared at the University of California Hospital at San Francisco and claimed to have attended the Louisiana State University School of Medicine and to have completed his medical course in India. While at the San Francisco hospital he wore a smock bearing the legend "Charity Hospital, New Orleans." He was described as being about 25 years of age, 5 feet 9 inches in height, weighing 160 pounds, and as having light brown hair, blue eyes and a sunburned complexion. He is said to have spoken with either a southern or a British accent. It seems that his principal attire was a green gabardine suit the jacket of which was double breasted and had brass buttons. He claimed that it was the yachting costume of the Bombay Yacht Club. He had also been observed wearing this jacket with white duck pants and also wearing a gold ring in the shape of a cobra, with green stones as eyes.

A San Francisco police report No. 338793 had been issued against him because on June 6 he had checked out from the University of California Medical School Library several magazines and books. While at the Medical School he claimed that his father was in charge of a hospital in Calcutta and that he was interested in observing obstetric cases. This apparently led to his receiving permission to sleep in one of the obstetric "ready" rooms. Since he made no attempts either to borrow money or to cash checks, his chief purpose in posing as a physician at the hospital seems to have been to obtain lodging.

With the permission of the hospital authorities, Faudree delivered an informal lecture at the nurses' home on the subject of medicine in India. He became friendly with two student nurses there and told them he was sailing for India on the S. S. *President Adams* on the 22d of June. He gave one of the girls the address of 39 Lahora Road, Calcutta, Bengal, India, as an address where he could receive mail. As a matter of fact, he had made no attempt to secure reservations on the *President Adams* but had made them for Calcutta on a Pan-American Airways plane, giving his address as the University of California Hospital.

By July 12 it had been intimated to the investigators that Faudree was located at the Mendocino State Hospital at Talmage, Calif. They also developed the information that his parents were located in Dayton, Ohio. By this time information had come from New Orleans that this individual was formerly an employee of the Charity Hospital of Louisiana under the name of Faudree de Fauche. He was an x-ray technician there from June 1, 1939, to March 9, 1940.

The investigators were able to locate him at the Mendocino institution where he had obtained employment commencing July 1 as a laboratory technician at a salary of \$160 per month less maintenance. He informed the superintendent of the institution that he had been referred there by the state board of health as an applicant for a temporary (noncivil service) appointment for the position.

At this time it developed that after he had left the employ of the Charity Hospital at New Orleans he went to San Francisco and stowed away on a freighter, which took him as far as Penang, but, not being allowed to land, he was returned to San Francisco June 1, about the time when he appeared at the University of California Medical School. In connection with

the position at the Mendocino State Hospital, he was issued a temporary laboratory technician's certificate on the basis of information, which he supplied, to the effect that he had attended the University of Calcutta, India, from September 1931 to June 1935, obtaining the degree of "B.Sc.Md.," had attended the School of Tropical Medicine in Calcutta from September 1935 to June 1939, when he obtained the degree "Doctor of Tropical Medicine," had thereafter worked in the Pathological Laboratory of the Carmichael Hospital, Calcutta, from June to October 1939, and claimed to have worked at the same institution as a "pathological intern" [sic]. He also claimed work in clinical diagnosis and claimed to have a provincial license in medicine in the province of Bengal, India.

On the basis of these facts it was decided to issue a complaint against Faudree for petty theft, and the special agent of the Board of Medical Examiners arrested him on July 24 in the laboratory of the Mendocino State Hospital, where he was able to recover the property which had been stolen from the Library of the University of California Medical School. "After intensive interrogation," Faudree admitted to the agent that he had never attended the University of Calcutta and that his whole story as to medical qualifications was false and, incidentally, that he had not intended to return the stolen property. He was booked at the Mendocino County Sheriff's office as No. 1259, and en route to San Francisco the agent had him booked again at the Sonoma County Sheriff's office as No. 6717.

Faudree appeared in the San Francisco municipal court before Judge Frank Dunn, in action 465612, on July 25, and pleaded guilty to petty theft (see clipping reproduced on this page). As the property had been recovered and

there was no indication of a previous record, either in California, Dayton, Ohio, his home town, or New Orleans, or in the Federal Bureau of Investigation, Judge Dunn imposed a sentence of six months in the county jail, which he suspended on condition that Faudree return to his parents' home in Dayton.

When apprehended, Faudree had in his possession a box of calling cards which he had had printed, and on which his name appeared with the prefix "Dr."

Robert Faudree may be only a first offender, but the ease with which he duped his victims might indicate previous experience or the likelihood of future performances.

The Alabama System.—On Feb. 19, 1875, the Alabama General Assembly passed a law designating the Medical Association of the State of Alabama as the state board of health and also designating county medical societies affiliated with the state medical association as boards of health for their respective counties. Thus Alabama became the first state in the Union to place its public health machinery beyond the political pale and to assure the people and its public health workers that the successful and competent performance of duty, and that alone, would determine continuance in service.—Baker, J. N.: *Alabama's Contribution to Public Health*, *Am. J. Pub. Health* 30:859 (Aug.) 1940.

'Scientist' Talks Himself Into Job—but Judge Has Final Say

Questioning Starts
When Medical School
Misses Its Books

Robert Gordon Faudree, 21, who

has been charged with stealing

books from the University of

California Medical School, was

questioned today by a special

agent of the state board of

medical examiners, came here to

Dayton, O., with 15 books from

the University of California

Medical School, and

convicted the books there that

he was a graduate of the University

of California and quite an expert

laboratory work, obstetrics and

tropical diseases.

He had around the school several

weeks, even delivering a lecture

on tropical diseases to student

nurses.

Then, according to Agent Hunter,

Faudree went to the Mendocino

State Hospital and talked himself

into a laboratory research job about

that time. He had at the U. C.

Medical School missed about \$25

worth of books. Suspicion pointed

to Faudree, and the board of medical

examiners was asked to investigate

him.

Agent Hunter decided a little

straight—from the horse's mouth

action was called for. He went to

the Mendocino hospital and, to

effect, told Faudree "you're a faker."

Faudree admitted he'd never been

closer to Calcutta than Mendocino

County. And his wide knowledge of

modern matters, he said, was ac-

quired while he worked for a short

time in Florida laboratory where

Dunn found him guilty of petty

theft. Faudree said he had

stolen the books from the

University of California Medical

School in Dayton.

ROBERT FAUDREE.

of Faudree's career
in California.

Correspondence

MYASTHENIA GRAVIS

To the Editor:—In reading the report by Dr. Robert C. Moehlig on his case of myasthenia gravis recently published (*Myasthenia Gravis: Treatment by Implantation of Desoxycorticosterone Acetate Pellets*, *THE JOURNAL*, July 13, p. 123), I was struck by the fact that little effort was made to confirm the diagnosis of this rare and somewhat obscure disease. The rapid onset of symptoms over a period of seven days to a point of orthopnea and prostrating fatigue is certainly unusual in myasthenia gravis. It appears from the examination that the patient had bilateral ptosis, dysphagia, dysarthria and general weakness, all symptoms which are consistent with the diagnosis, but it is not clearly indicated that he had the primary symptom of myasthenia gravis, namely fatigue on muscular motion with recovery after rest. This, moreover, was not brought out by the Jolly reactions, nor is there a record of the other tests now commonly used to confirm the diagnosis. These tests are the "prostigmine test," devised by a number of workers to evaluate the effect of prostigmine when injected intramuscularly, electromyograms, ergograms and fluoroscopic studies of barium ingestion. The most important of these tests is the "prostigmine test," which should always be done if there is any doubt about the diagnosis and is particularly important in a case such as that described by Dr. Moehlig when the diagnosis may be not entirely clear. If one is to draw any conclusions in regard to any type of therapy, one should be certain that the patient under observation has the disease in question in an unmistakable and unequivocal manner.

One notes with interest, moreover, that the patient was given quinine as one of the forms of treatment. It has been well recognized in recent years that quinine is one of the drugs that will make the symptoms of myasthenia gravis more pronounced, whereas its pharmacologic antagonist, prostigmine, will improve the symptoms. There is a certain danger in using quinine, for the symptoms of myasthenia gravis may become so pronounced under medication with this drug that respiratory failure will ensue. Dr. Moehlig reports only "unpleasant effects" of this drug and does not make it clear what these effects were.

To evaluate any form of treatment in a disease such as myasthenia gravis is indeed difficult. The periods of remission may be acute and practically complete. Patients as seriously ill as the one described by Dr. Moehlig have been known to recover their normal state of health within a week or less. One would wish, therefore, before conclusions are drawn about the efficacy of a drug or glandular preparation to be not only as certain as possible in regard to the diagnosis of this unusual disease but also sure that the patient was not passing into a stage of remission rather than a stage of recovery due to a specific medication.

HENRY R. VIETS, M.D., Boston.

To the Editor:—I wish to call your attention to the dangerously misleading impression that might be read into Dr. R. C. Moehlig's report of a case of myasthenia gravis in *THE JOURNAL*, July 13. From the way in which the therapeutic trial of quinine is referred to in this report, one might easily deduce that the drug has been elsewhere reportedly used successfully in the treatment of this disease, especially since it was here administered together with aminoacetic acid. Actually, quinine is definitely contraindicated, as was reported by Kennedy and Wolf (*Arch. Neurol. & Psychiat.* 37:68 [Jan.] 1937). Later, Harvey showed that quinine has a curare-like action, as he reported in *THE JOURNAL*, April 22, 1939, page 1562, and thus its administration enhances the curare-like paralysis of myas-

thenia gravis. I have seen 10 grains (0.65 Gm.) of quinine produce an alarming state in a moderately severe case of myasthenia gravis.

It is regrettable that no mention is made of the use of prostigmine to verify the diagnosis of the case reported. As it is, the clinical course described can just as easily be interpreted as a textbook picture of nonfatal botulism. The abrupt onset is certainly more typical of botulism than of myasthenia gravis.

In any event, it is to be hoped that the further progress of the case will be reported, no matter what the outcome, so that one may learn whether the improvement reported was spontaneous or a direct result of the substitution therapy with desoxycorticosterone.

LEO D. FREYBERG, M.D., Granville, N. Y.

CHRONIC CARBON MONOXIDE POISONING

To the Editor:—Because of the number of cases of alleged chronic carbon monoxide poisoning which are getting into the courts, the article entitled "Carbon Monoxide—A Domestic Hazard, with Especial Reference to the Problem in West Virginia," by Harvey G. Beck, Wilmer H. Schulze and George M. Suter, which appeared in *THE JOURNAL*, July 6, page 1, deserves comment.

There is no question of the importance of true acute carbon monoxide poisoning which leads to coma and death or to complete recovery except for neurologic complications in rare instances. These authors imply that chronic carbon monoxide poisoning is a common cause of a great multiplicity of symptoms. In only one or two of their cases do the criteria given seem adequate to establish significant exposure to carbon monoxide. The number of patients in a similar environment who did not show any symptoms is not mentioned. In only two cases is the blood level of carbon monoxide hemoglobin mentioned, and in these cases the time after exposure is not stated. Figures are not given as to the actual concentration of carbon monoxide found in the localities in which persons were alleged to be exposed, although in one or two instances a dangerous concentration was said to have been found without the figure being stated.

Among the statements that seem open to question are the following: on page 2 "Coronary thrombosis has repeatedly been observed clinically and at autopsy as well as in experimental animals in states of carbon monoxide anoxemia"; on page 6 "The basal metabolism is uniformly low in carbon monoxide anoxemia," and the implication on page 3 that a red blood cell count of over 5,000,000 constitutes a polycythemia. Actually, the average red cell count for men is 5,400,000, and counts well over 6,000,000 are not infrequently encountered in healthy men.

The authors fail to give the criteria by which they exclude other etiologies for the symptoms mentioned. The fact that they mention specifically such a wide variety of diseases or syndromes simulated by these symptoms, including angina pectoris, multiple sclerosis, hemiplegia, tetany, neuroses, psychoses, cardiospasm, pylorospasm, spastic constipation, gastric achylia, nocturia, dysuria, anemia and polycythemia, to mention only a few, suggests that other diagnoses rather than carbon monoxide poisoning account for these symptoms.

Other conditions are much more important and common causes of the symptoms mentioned. The authors fail to present evidence that the symptoms mentioned were actually due to exposure to carbon monoxide. Carefully controlled experiments by Yandell Henderson and by the U. S. Bureau of Mines failed to show any significant sequelae from exposures to carbon monoxide not leading to prolonged unconsciousness.

EDWIN E. OSGOOD, M.D.

JOSEPH BEEMAN, M.D.

Portland, Ore.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

POLIOMYELITIS AND TONSILLECTOMY

To the Editor:—Some time ago I noticed an article in *The Journal* which tended to show that it was hazardous to do tonsillectomies during the fall season for the reason that it increased liability to the contraction of infantile paralysis, the latter disease being more prevalent at that season of the year. Is this the contention of specialists in general and has the contention been proved to a satisfactory degree? It has always seemed to me that more patients submit to tonsillectomy just before the beginning of the school year in September than at any other time. Any information you can give me along this line will be appreciated.

M.D., Iowa.

Because of the importance of this question it was submitted to two consultants, whose respective replies follow:

ANSWER.—There is little doubt that tonsillectomy predisposes to poliomyelitis of the bulbar type only. This predisposition has been noted whenever it has been sought for in the epidemics of the last five years. This phenomenon was first reported by Aycock and Luther in 1929 (*New England J. Med.* 200:164 [Jan. 24] 1929). These authors noted that, of thirty-six children who had contracted poliomyelitis and who also had tonsillectomies within a year, the operation had been performed from seventeen to eighteen days preceding the onset of disease in sixteen. This interval corresponds exactly with the known incubation period of the disease in man.

In most epidemics of poliomyelitis the bulbar type makes up but 10 to 15 per cent of the total cases. It is thought that tonsillectomy bares nerve endings in the tonsillopharyngeal area, allowing the virus to enter the nervous system over these free nerve endings, it being assumed that such a person was a carrier of the virus at the time the operation was performed. That human carriage of virus is not infrequent has been shown by several investigators. Not only is the virus probably carried in the nasopharynx in certain persons, but it is also harbored in the gastrointestinal secretions, certainly in the active cases of convalescents of the disease. It has been detected in two cases in sewage.

The most recent and complete report on this question is to be found in the article by Stellerman and Fisher, "Acute Bulbar Poliomyelitis Following Recent Tonsillectomy and Adenoidectomy," in the *American Journal of Diseases of Children* (56:778 [Oct.] 1938).

Experimental studies by Sabin on monkeys (*THE JOURNAL*, Aug. 13, 1938, p. 605) have shown that the tonsillopharyngeal region is more highly sensitive to poliomyelitis virus than many regions of the body, and the type of the disease so produced when experimental is bulbar and bulbospinal. This author was successful in producing experimental poliomyelitis by first removing tonsils surgically and then spraying virus into the throat. The experimental disease was produced only when spray containing the virus was administered to the experimental animal within a few hours after surgical removal of the tonsils.

Trauma elsewhere in the oral cavity may possibly predispose to poliomyelitis infection. A report by Gard (Nouvelles recherches sur l'épidémiologie de la poliomyélite, Office international d'hygiène publique 30:933 [May] 1938) states that two cases of poliomyelitis followed extraction of teeth, in both of these cases the onset of disease corresponding to the known incubation period of poliomyelitis in man. There has been no confirmation as yet.

It would appear that in the absence of an epidemic there is little or no more hazard of submitting children to tonsillectomy during the summer and fall months than at any other time.

In light of the available information, one would be inclined to defer tonsillectomy in the presence of an epidemic.

ANSWER.—Clinically there does not appear to be any evidence that a tonsillectomy is a predisposing factor to infantile paralysis. This is borne out by the great number of operations performed in the fall of the year without any apparent material increase in the number of cases of infantile paralysis.

Although a number of investigators have reported, in different series of observations, a small group of cases of infantile paralysis of the bulbar type that occurred at varying intervals after tonsillectomy, it is a question whether or not this finding is coincidental. Sabin (*Experimental Poliomyelitis by the Ton-*

sillopharyngeal Route, *THE JOURNAL*, Aug. 13, 1938, p. 605), in experimental work on monkeys, has shown that bulbar paralysis can occur more readily after a tonsillectomy, progressing along the local peripheral nerves. To occur postoperatively the virus would have to be present in secretions or in the tonsils during the operation, and infection would be facilitated by any procedure involving injections or postoperative suturing.

From these observations it can be deduced that it is unwise to perform a tonsillectomy in the presence of a local epidemic of this disease, but it is questionable in the opinion of most men whether one should adopt a "rule of thumb" to avoid a tonsillectomy in the fall merely on the ground that there is a greater prevalence of poliomyelitis at that time.

Concerning the question of the incidence of tonsillectomies, certain localities show a preponderance of operations immediately following the closing of the school term, with a second but smaller frequency peak in September. This varies in different parts of the country.

COLOR BLINDNESS

To the Editor:—A white man aged 55 shows complete red-green color blindness with the Ishihara chart. However, he passes the Jennings color test perfectly. He has never noticed any difficulty in recognizing colors. He worked in millinery and in piece goods departments where matching colors is essential, and he was acknowledged to be one of the best color matchers in the store. He has no difficulty with traffic lights, recognizing the red, green and yellow lights instantaneously. Can you explain why he should be classed as red-green color blind, and if color blindness was a test for employment would the Ishihara or the Jennings test be accepted? Also, can you explain why he should be red-green color blind with one test and not with the other?

M.D., Tennessee.

ANSWER.—It is common knowledge that an anomalous deuteranope will be unable to read the red-green figures in the Ishihara and Stilling charts and still be able to pick out red and green colors accurately. This is due to the fact that the colors in the Ishihara and Stilling charts are borderline, the greens being almost gray, and that is the point at which these patients have difficulty. The latest edition of the Ishihara chart is not satisfactory and only the first edition should be used for testing. It is reliable for most color blind patients. The army has discarded both the Ishihara and Stilling charts for color blind testing because of their failure in cases such as the one described and now relies entirely on the old fashioned skeins of yarn for testing color blindness.

FECAL STREPTOCOCCI AND URTICARIA

To the Editor:—We have a patient with chronic urticaria of about sixteen months' duration. She has had the usual skin sensitization tests and has been getting theelin and nonspecific desensitization treatments with typhoid vaccine. The only specific desensitization treatment has been with a vaccine of *Streptococcus viridans* found in the stool in nearly pure culture. The use of this vaccine subcutaneously in the proper dosage has resulted in the disappearance of the urticarial eruption except for the appearance of a few lesions when the interval between treatments has been too prolonged, and the improvement in her general condition has kept pace with the cutaneous improvement. What treatment, if any, might be available to eradicate the intestinal focus of sensitization? This method of treatment, if successful, might obviate the necessity for hypodermic treatment with much colder and more satisfactory results. The positive culture of *Streptococcus viridans* was obtained from an ordinary stool, and it would seem that the infection might be in the colon or lower part of the colon. I have had in mind the use of gentian violet coated capsules prepared so as to dissolve in the colon, *Bacillus acidophilus*, sulfonilamide or some derivative.

M.D., Arizona.

ANSWER.—*Streptococcus viridans* is so commonly found in the stools of human beings that its importance in such a cutaneous condition seems doubtful.

Much has been said and written concerning the intestine as a focus in chronic diseases. Often apparent relationship between poor intestinal elimination and such conditions as arthritis, chronic cutaneous disease and general debility seems to be at hand. No adequate proof of such a relationship, however, is available. True enough, when proper bowel function is established, or even after intestinal irrigations are instituted, improvement in the systemic condition is sometimes noted. In individuals with inflammatory diseases of the bowel, such as ulcerative colitis, systemic complications like those mentioned may occur. In these cases the eradication of the colitis will frequently result in the disappearance of the cutaneous or other systemic manifestations. However, when no bowel disease is noted and only *Streptococcus viridans* in the stool is present, the eradication of this streptococcus, changing the intestinal flora through diet and the like, will rarely if ever have any effect on the cutaneous condition. In short, it is most difficult to establish any relation between the presence of this organism and a cutaneous condition such as urticaria.

However, bacterins prepared from organisms isolated from the stools, even though actual lesions in the bowel are absent,

have been commonly used. It has also been a common practice to change intestinal flora by giving acidophilus milk, but such a change is usually temporary. Of the various drugs mentioned, gentian violet could be used without probable harmful effect. All in all, it seems rather doubtful that the cutaneous condition could be aided much by removing *Streptococcus viridans* from the stool or by desensitizing the patient against it.

The best and most discussed method as well as the one yielding apparent results in some cases so far as eradicating the streptococci seems to be by the injection of a bacterin prepared from the streptococci in individual cases.

VITAMIN D FOR ADULTS

To the Editor:—At a recent postgraduate institute a speaker stated that the administration of vitamin D in the form of cod liver oil, viosterol and the like should be restricted to children and is contraindicated for all adults, as this vitamin causes demineralization of bones. Will you kindly advise me whether this opinion is commonly held true or not?

Calvert R. Toy, M.D., New Brunswick, N. J.

ANSWER:—There is no evidence that a moderate amount of vitamin D causes demineralization of the bones of adults or produces any adverse effects. Indeed there is some evidence that reasonable amounts of vitamin D, such as 400 U. S. P. units daily, may be beneficial, particularly during adolescence. While no need for supplies of vitamin D other than the effect produced by ordinary exposure to sunlight has been shown for the average normal adult, there is considerable evidence that many women require vitamin D in order to remain in calcium equilibrium during pregnancy and lactation.

VASECTOMY AND PERSISTENCE OF SPERMATOZOA

To the Editor:—What observations have been made as to the length of time spermatozoa can persist in the seminal vesicles when their testicular source of supply has been blocked by a vasectomy? I recently have seen two patients who had a vas resection performed over a year ago but who continue to show occasional nannotile spermatozoa on microscopic examination of the ejaculate. I can hardly conceive of an opening in the vas so small as to allow only the passage of a few spermatozoa; neither can I believe that spermatozoa will continue to be present in the vesicles for as long a period as a year.

M.D., Oklahoma.

ANSWER:—The consensus among practicing urologists is in effect that spermatozoa may remain in the seminal vesicles after a bilateral vasectomy for as long a period as from twelve to sixteen weeks. This depends on the frequency of sexual intercourse. Some men are of the opinion that sperms lose their motility at the end of about forty-five or fifty days after vasectomy. Most important in a situation such as this is to be definitely sure that a vasectomy has actually been performed and that the cut ends of the vas deferens were widely separated. There are instances in which the vas was simply cut and not widely separated, the vas grew together and the lumen was reestablished and hence sperms were found. A similar situation may also occur in cases in which subcutaneous ligation of the vas has been performed.

CONGENITAL ENTROPION

To the Editor:—I have recently seen a 3 months old baby with bilateral entropion of the lower lids, which the mother states has been present for about two months. There is only slight inflammation of the bulbar conjunctiva and apparently there are no subjective symptoms. The baby is quite plump, there is apparently no edema of the lids and the urine is normal. Please suggest treatment and prognosis without treatment.

Curtis M. Galt, M.D., Monteca, Calif.

ANSWER:—Congenital entropion is by no means a rare condition and usually under conservative treatment relieves itself after a short period of from three to six months. If the lashes are so turned in that they strike both the conjunctiva and the cornea, irritation of these tissues may call for more active treatment. A palliative measure which has good results is the use of adhesive tape to pull the lid out. The upper portion of the tape should be placed just below the lash line and as the lid is pulled away from the eyeball the remainder of the strip is pasted on the cheek. If such procedures are inadequate, surgery may be indicated. The simplest surgical procedure is the one made so well known by Dr. Ziegler of Philadelphia, which is as follows: Just below the lash line on the surface of the skin, small cautery punctures are made throughout the extent of the entropion. When these scars heal there is definite tendency for the lid to turn out and the skin surface, after a short time, shows no scarring. Other surgical procedures are the removal of a strip of skin below the lash line and connecting of the incised area. At times it may be necessary to remove a portion of the orbicularis muscles for the best effect. As a rule, the prognosis in this type of entropion is good without treatment.

VISUAL DISTURBANCES FROM DIGITALIS

To the Editor:—I digitalized a man aged 74 with generalized arteriosclerosis and chronic auricular fibrillation. Owing to an error in reading his weight on a new scale, I gave him in two days about 0.3 Gm. of digitalis over that required on the basis of 0.1 Gm. per 10 pounds (4.5 Kg.) of body weight. He had mild nausea and vomited once, but his most troublesome toxic symptom, which has persisted two weeks without amelioration, is green vision, especially when he looks at lights. I stopped the maintenance dose for five days, then put him back on 0.1 Gm. a day. Is this toxic effect dangerous? Does it cause any permanent damage? Can I do anything to rid him of it? How long, on the average, do such visual disturbances persist if digitalis maintenance doses are continued?

M.D., Ohio.

ANSWER:—Disturbances of vision, especially seeing various colored lights and occasionally transient blindness, has long been noted to occur during the administration of digitalis. When it occurs, it is evidence of excess dosage, although on occasion it may occur with small doses as a result of idiosyncrasy. No permanent harmful effects will result from this disturbance in vision provided the digitalis is discontinued. It is a definite indication that digitalis must be stopped and discontinued until all symptoms have disappeared. Care should be employed in readministering digitalis to such patients, since the symptoms can easily recur. It is a wise procedure to explore other varieties of digitalis leaf, since it occasionally happens that the patient is more tolerant to a different species of digitalis leaf or to some squill product. There is no specific antidote for this complication other than the prompt discontinuance of the digitalis. It must be recalled that digitalis has a large cumulative effect and the reduction in dosage alone may not be sufficient to reduce the concentration of digitalis in the body tissues. This accounts for the continuation of the symptoms with the administration of daily doses of 0.1 Gm. It should be reemphasized that the digitalis should be stopped entirely when this symptom is found.

PROBABLE FRÖHLICH SYNDROME

To the Editor:—A boy who was 14 years old on November 27 is 5 feet 3 inches (160 cm.) tall, weighs 145 pounds (66 Kg.), is from 34 to 37 inches (86 to 94 cm., expiration-inspiration) around the chest, 32 inches (81 cm.) around the waist and 40 inches (102 cm.) around the trochanters. The inseam is 30 inches (76 cm.). He has developed no secondary sex characteristics. The testes and penis are small. He is a typical moderately fat boy type. He excels in school work, has a brilliant personality and is not feminine in the least way. He is well liked by his playmates. His mother is about 5 feet 4 inches (163 cm.) tall and comes from an average size normal family. The father is 6 feet 1 inch (185 cm.) tall and weighs about 235 pounds (107 Kg.). He has always been well developed muscularly and always a little overweight. He played college football. He did not develop sexually until he was almost 17 years old, and although his sex organs have always been small he has always been virile. The father's hair became thin at 21 years of age, when hair began to develop all over the body. The paternal grandfather was of the same type, with two uncles and two cousins of similar body build. Do you think it would be advisable to give the boy some growth stimulating hormone? If so please advise which preparations you consider best.

M.D., Iowa.

ANSWER:—This description fits Fröhllich's syndrome, although the actual size of development of the genitalia is not definite. Undoubtedly such a patient ought to be placed on a reducing diet in order to bring the obesity under control. Endocrine therapy is not necessary or advisable for this purpose. Whether or not any growth promoting hormone should be used would depend on the rate at which the boy has been growing in the last year and on whether x-ray study of the femurs showed that the epiphyses are still nonunited so that growth can continue. If he has not been growing approximately 2 inches (5 cm.) in the last year and if the epiphyses are still not united, then growth promoting pituitary hormone would probably be indicated.

SEDIMENTATION TEST IN RHEUMATIC FEVER

To the Editor:—What is the prevailing attitude now on using the sedimentation rate as a criterion for regulating activity in adults or children following an attack of acute rheumatic arthritis?

I. H. Wilson, M.D., Worthington, Minn.

ANSWER:—There appears to be general agreement among physicians interested in rheumatic fever that a rapid sedimentation rate is of considerable importance in the evaluation of the presence of active rheumatic fever. It is perhaps the most valuable single nonspecific laboratory test. An elevated white blood count and a prolongation of auriculoventricular conduction time by electrocardiogram are also helpful. Other causes of a fast sedimentation rate must be considered prior to its acceptance as indicating active rheumatic fever. It must also be remembered that the sedimentation rate may remain fast for two or three weeks following infection of the upper respiratory tract in non-rheumatic as well as rheumatic individuals.

There is, however, a difference between the regulation of physical activity of rheumatic fever patients and the evaluation of the presence or absence of active rheumatic fever. The sedimentation rate is generally valuable in determining the latter. Many other factors must be considered in directing the physical activity of a patient with recent clinical rheumatic fever. In general, most workers strive to restrict the patient's activity, even to give bed rest, as long as rheumatic fever continues to be active. Laboratory tests may be persistently abnormal without clinical symptoms, indicating a continuation of mild rheumatic fever. This period of active rheumatic fever may last for months or even years, and hence the problem is a difficult one. The sedimentation rate is, however, a valuable guide in following the course of the active rheumatic fever in a given case.

MERCURIAL DISINFECTANTS

To the Editor:—We recently had in our office a detail man who made the statement that the United States Public Health Service refused to accept mercuric cyanide as a potent antiseptic even if used in a solution of 1:300 for fifteen minutes. He made the statement that urethral catheters could not be sterilized by the drip method if mercuric cyanide 1:500 was used. This, he said, was also true of urethral catheters which were placed in mercuric cyanide 1:500 and left for thirty minutes. He stated that the interior of the catheter continued to yield viable staphylococci when it had been so infected. Please give us what data you have with regard to this subject.

W. G. Schulte, M.D., Salt Lake City.

ANSWER:—Not only mercuric cyanide but also other mercurial disinfectants, when used in the concentrations usually recommended, were found by Brewer (*THE JOURNAL*, May 20, 1939, p. 2009) not to kill bacterial spores exposed to the disinfectants for twenty-four hours. Nonsporulating bacteria are more easily killed. Instruments with hinges, crevices or canals are not likely to be sterilized by chemical solutions unless there is a forced circulation of the solutions through them. The mercurial compounds are known to be much more bacteriostatic than bactericidal. Under certain circumstances they may be useful antiseptics but are not good sterilizing agents.

CHAULMOOGRA OIL FOR LARYNGEAL TUBERCULOSIS

To the Editor:—Is the painting of the larynx with chaulmoogra oil of recognized value in the treatment of tuberculous laryngitis and, if so, would it be likely to cause an acute hemorrhagic nephritis over a period of about one month?

C. W. Atherton, M.D., Marshall, Ill.

ANSWER:—It is debatable whether chaulmoogra oil is of real value in the cure of tuberculous laryngitis. Certainly the enthusiasm for this therapy is not what it once was, and few have achieved the excellent results of some of the early reporters.

Spencer believes that the oil has some value as a mild, palliative and perhaps curative remedy; Myerson, however, who also has had a large experience, is convinced that the oil does not have curative effect but is of value as a temporary soothing and cleansing agent. He does not believe that any larynx which it has apparently cured would not have been healed without it.

The results in animal experimentation have not been remarkable.

It is not likely that chaulmoogra oil acts as the cause of acute hemorrhagic nephritis. True, injections of sodium hydriocarpate, a closely related compound with similar actions, has been reported to have produced albuminuria and hematuria in rabbits and dogs. Reports of such toxic effects in man, however, when the drug is used locally, as in the case of tuberculous laryngitis, are wanting.

SWIMMING IN PREGNANCY

To the Editor:—Is there any objection to a primipara, apparently in good health, going swimming? I have given advice, perhaps old fashioned, against swimming because of the sudden shock to a person who is already carrying a double load.

M.D., New York.

ANSWER:—There is no serious objection to a healthy primipara swimming during the first seven months of the gestation. The water in which the patient swims should be relatively clean and warm. The water at the crowded beaches or large urban centers on hot summer days is usually contaminated and is not a desirable place for the pregnant patient. Lower genital tract infections can and do occur in such environments.

HYPERKERATOTIC EPIDERMOPHYTOSIS

To the Editor:—A woman aged 54 has had a dermatitis of both hands and feet for twenty-six months. This was diagnosed as epidermophytosis by the family physician and a dermatologist. She received roentgen treatments every two weeks for eight months before consulting a specialist. He treated her with potassium permanganate and also various ointments containing coal tar products and salicylic acid with no results. She has been using numerous proprietary drugs and had "shots" given by a cultist. I saw her about four weeks ago, at which time the hands were covered on the palms by thickened tough skin which, when removed, left a red sensitive surface which itches and burns. The patient was off work as a beauty operator for five months while the lesions were in the weeping stage but noticed slight improvement. No cutaneous tests have been done; the blood count was normal except for 11,200 white cells, with a normal differential count. The only improvement followed accidental use of formaldehyde on the hands. What tests would you suggest? Would formaldehyde be safe to use and if so what strength? Would sodium thiosulfate or any other form of medication offer anything? Would roentgen therapy be safe to use again in combination with local fungicides?

M.D., Indiana.

ANSWER:—As the patient's work is that of a beauty operator, one might suspect an occupational dermatitis if her feet were not also involved. In cases of this type it is difficult to make a positive diagnosis, but from the history given the condition is most probably a hyperkeratotic type of epidermophytosis. In all hyperkeratotic lesions on the palms and soles the possibility of previous arsenic ingestion should be considered. The patient should not have any more radiotherapy. Sodium thiosulfate 15 grains (1 Gm.) several times a week may prove to be of value. Warm soaks twice daily in a solution of sodium borate followed by the application of salicylic acid and benzoic acid ointment should also prove to be of benefit. The first ointment should consist of salicylic acid 1 part, benzoic acid 2 parts and rosewater ointment and petrolatum to make 30 parts. Later the strength of this ointment can be doubled.

ACID AND ALKALI BURNS

To the Editor:—What is the present method of treating industrial caustic burns?

M.D., Mississippi.

ANSWER:—E. C. Davidson (*Ann. Surg.* 85:481 [April] 1927) made an experimental study of the treatment of acid and alkali burns. He concluded that "the results obtained in the treatment of experimentally produced alkali and acid burns were decidedly better when the caustic agent was removed by dilution with water than when rendered inert by neutralization. When treatment by neutralization is employed it should only be employed after the maximum amount of the caustic has been removed by thorough washing."

CONCERNING RADIATION AND HEREDITY—DIAGNOSTIC X-RAY AND FETAL ABNORMALITIES

To the Editor:—On page 1836, *The Journal*, Nov. 27, 1937, a physician asks to be enlightened on the chances a woman has of producing normal children when fertility has been temporarily suspended by x-rays and radium. Your answer states that "her chances for having normal children are just as good as those of women who have not received radiation therapy." This answer is correct as far as the immediate offspring is concerned; but injury may become manifest in the progeny of her children. Not sufficient time has elapsed to observe whether or not the human race is just as susceptible to such remote injuries as numerous animal species (among them animals as closely related to us as mice). The next sentence of your answer reads "There has been controversy on this subject, but the consensus is that radiation therapy applied before fertilization of an ovum does no harm." This too calls for some qualification. To quote just one of the authentic dissenting opinions I refer to Colwell and Russ, who advise strongly against temporary sterilization of women who may afterward bear children (X-Ray and Radium Injuries, London, Oxford University Press, 1934). More recently at least two prominent American authors have gone on record as being of the same opinion.

On page 2455, *The Journal*, June 10, 1939, the question is raised whether diagnostic x-ray exposures during pregnancy may cause fetal monstrosities. After setting forth the conventional teaching that diagnostic x-ray procedures during pregnancy, if not applied in unduly large quantity, do not harm the child or the ovaries, *The Journal* continues "Only recently have any objections been heard to the foregoing statement, but these are from abroad and are deductions from experiments on plants." The objections originated in the United States and are based primarily and mainly on animal experiments. (Muller, H. J.: *Röntgen Rays and Heredity* in Otto Glasser's book "The Science of Radiology," Springfield, Ill., Charles C. Thomas, 1933). These objections are made in view of possible damage to later generations. The subject matter underlying both these queries and their answers, namely, radiation and heredity, is involved and complex. At the same time it is of great practical importance to every physician who applies or has others apply x-rays for diagnosis and treatment, even though this importance may not be sufficiently appreciated. I have made an attempt to present the subject at greater length and in nontechnical language in my article "The Importance of a New X-Ray Effect for Our Daily Diagnostic and Therapeutic X-Ray Work" (*New York State J. Med.*, Aug. 1, 1940). An extensive bibliography can be found in this article.

Siegfried W. Westing, M.D., Brooklyn.

Medical Examinations and Licensure

COMING EXAMINATIONS

BOARDS OF MEDICAL EXAMINERS

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, August 31, page 800.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II, Sept. 11-13, to be given in medical centers having five or more candidates desiring to take the examination. Part III, Baltimore and New York during October and Boston during November. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Various centers, Feb. 20. Final date for filing application is December 21. *Oral*. Cleveland, May 31-June 1. Final date for filing application is April 1. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written*. Various centers, Oct. 28. Applications must be on file not later than Sept. 16. *Oral*. Chicago, Dec. 6-7. Applications for Group A must be on file not later than Nov. 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Chicago, Oct. 18-19. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville, Ky.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Part I Group B examinations, locally, Jan. 4, 1941, at 2:00 P. M. Part II, Groups A and B, Cleveland, Ohio, June 1941, immediately prior to opening of A. M. A. meeting. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh, Pa.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Cleveland, Oct. 5. *Written*. Various centers, March 8. The only written examination during 1941. Applications must be on file not later than Dec. 1. A special oral and clinical examination will be held on the Pacific Coast during 1941 providing there will be enough candidates to warrant it. Applications for this examination should be on file not later than Sept. 15. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Oral and written*. New Orleans, January 1941. Final date for filing application is November 15. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF PEDIATRICS: New York, March 30-31. Following the Region I meeting of the American Academy of Pediatrics, Chicago, May 18. Following the Region III meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: *Oral*. New York, December 18-19. Final date for filing application is October 8. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Boston, Sept. 26-29. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written*. Part I. Various centers, October 21. Final date for filing application is September 15. Sec., Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Oral and written*. Chicago, February 1941. Applications must be on file not later than Oct. 15. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Florida June Report

Dr. William M. Rowlett, secretary, Florida State Board of Medical Examiners, reports the written examination for medical licensure held at Tampa, June 17-18, 1940. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Eighty-one candidates were examined, seventy-eight of whom passed and three failed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
George Washington University School of Medicine.....(1932)			1

* This applicant has received the M.B. degree and will receive the M.D. degree on completion of internship.

Tennessee June Report

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination for medical licensure held at Knoxville, Memphis and Nashville, June 14-15, 1940. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and eighteen candidates were examined, 117 of whom passed and one failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....(1940)	85.8		90.3

Book Notices

Proximate Composition of American Food Materials. By Charlotte Chathfield, Foods and Nutrition Specialist, and Georgan Adams, Associate Food Chemist, Foods and Nutrition Division, Bureau of Home Economics, United States Department of Agriculture Circular No. 549. Paper. Price, 15 cents. Pp. 92. Washington, D. C.: Supt. of Doc., Government Printing Office, 1940.

The comprehensive tables prepared by Atwater and Bryant on the chemical composition of foods have not been revised since 1906. It is appropriate therefore that the Department of Agriculture again should issue an authoritative booklet on the composition of foods. The data in this report were obtained chiefly from published records of analysis that have been made in many laboratories by different investigators using different methods. A considerable number of results of unpublished analyses likewise are included, but the authors state that for the most part they have studied the original records critically. Data are provided for about 2,000 foods. The information includes the name of the food, the nature of the sample, the basis of the analytical figures, the percentage of refuse and of the constituents of the edible portion in terms of water, protein, fat, ash, total carbohydrates, fiber, sugars, starch and acid, and fuel value per hundred grams and per pound. The tables are more conveniently arranged than they have been in many compilations because the individual foods are listed alphabetically. The report includes many data on the composition of vegetables, fruits and meats heretofore available only in separate publications. The tables will prove useful for dietary calculations and invaluable for the approximate estimation of dietary ingredients such as is necessary in formulating a diet for persons with diabetes. There is a separate table listing fruits and vegetables in groups containing about 3 per cent carbohydrate, about 6 per cent carbohydrate and so on, according to a familiar classification.

Unlike the compilation by Atwater and Bryant, the present tables do not provide a range of values or the number of analyses. While the authors state in their introductory remarks that variations are to be expected in foods, the tables provide only the average values, and this fact may be easily overlooked. Raw potatoes, for example, are stated to contain 19.1 per cent of total carbohydrates. The tables of Atwater and Bryant show the total carbohydrates for this food to be from 13.5 to 27.4 per cent, with the average of 136 analyses as 18.4 per cent. In this connection the title of the present report may be especially appropriate if "proximate" is taken to mean "almost correct."

It would be helpful to many users of such a compilation if somewhat larger type could be used for the tables. While the present compilation may be of inestimable value, particularly for the formulation of diets for diabetic patients, there are other data which are assuming great importance for the physician. The amount of calcium, phosphorus and iron in foods would constitute useful knowledge. Even data on the relative amounts of sodium and potassium in foods is coming to assume importance in the modern dietary management of Addison's disease. Perhaps such data may be made available in future compilations just as there now is a fairly recent compilation of data regarding the vitamin content of foods.

Neoplastic Diseases: A Treatise on Tumors. By James Ewing, A.M., M.D., Sc.D., Professor of Oncology at Cornell University Medical College, New York City. Fourth edition. Cloth. Price, \$14. Pp. 1,160, with 581 illustrations. Philadelphia & London: W. B. Saunders Company, 1940.

Twelve years has elapsed since the previous edition of this great book was published. A multitude of contributions on neoplastic diseases has appeared from all points of the scientific circle—physics, chemistry, physiology, pathology, clinical medicine and genetics—in the interim, necessitating extensive revision of many sections and the rewriting of some of the forty-nine chapters of the book. Dr. Ewing is most ably fitted to present a critical review of this expanding knowledge and to collect from the innumerable sources the essential facts and principles. He has omitted much historical material from this edition to make room for new contributions and yet has kept the volume within reasonable space. The general plan of the book remains the same. The author combats the theory that tumors fall into a limited number of grand classes in which the forms occurring

in the several organs are so nearly related as to be virtually identical. The practicing physician has been content to regard all cases of general classes of tumors as equivalent conditions without regard to the organ involved and to treat the members of each class alike. On this theory was born the conception of a universal causative agent of malignant tumors, a point of view that has greatly retarded progress. To combat this conception, Dr. Ewing analyzes the many factors which meet in the inception of tumors. He emphasizes the dependence of the clinical course on histologic structure, traces the histogenesis and contrasts the striking clinical features which often are characteristic of different tumors. The first nine chapters are of a general nature, dealing with theories, the chemistry of tumors, pathology, malignancy, metastases, experimental cancer research and the history, definition and classification of tumors. In the other forty chapters, which the author terms collectively "special oncology," he takes up different kinds of tumors, beginning with fibromas, which are discussed with regard to sites, origin, clinical types and histologic groups. Other chapters are on tumors of the breast, carcinoma of the stomach, maxillary tumors of dental origin, tumors of the kidney, tumors of the testes, myeloma, tumors of the hypophysis, teratology, tumors of nerve trunks, brain tumors, lymphoma, endothelial sarcoma and tumors of the pancreas. The illustrations have been made almost entirely from photographs. The extensive bibliography is arranged in the back of the book under the same general headings as are the chapters.

Vitamin D: Chemistry, Physiology, Pharmacology, Pathology, Experimental and Clinical Investigations. By C. I. Reed, A.M., Ph.D., Associate Professor in Physiology, H. C. Struck, M.S., Ph.D., Associate in Physiology, and I. E. Steck, M.S., M.D., Instructor in Physiology and in Medicine, Department of Physiology and Department of Medicine, College of Medicine, University of Illinois, Chicago. Cloth. Price, \$4.50. Pp. 389, with 13 illustrations. Chicago: University of Chicago Press, 1939.

The authors of this book are among the chief proponents of the use of massive doses of vitamin D in the treatment of arthritis, "pollinosis" and a variety of clinical conditions other than rickets. Therefore it is not surprising to find that this is not the conventional review of vitamin D which its title suggests but, on the contrary, is essentially a defense of the empirical use of vitamin D as a pharmacologic agent. The earlier chapters of the book are devoted to a brief review of the chemistry of vitamin D, the relative potency of various forms of the vitamin (including the several forms of vitamin D milk), a description of biologic and chemical methods for determining vitamin D, and a discussion of the physiologic effects of the vitamin, including its possible mode of action in the prevention or healing of rickets. Throughout the review much space is given to reports of the work of foreign investigators, although these reports are not always critically evaluated and although the results may not have been adequately confirmed. The review of the literature is not as well balanced as could be desired, and although in places the review reads smoothly, all too frequently the reader is confused by the lack of adequate classification and by the quotation of conflicting data with no advance warning that they will be conflicting. Too often also articles are reviewed which the authors state have been available only in abstract. It is difficult to understand why the description of methods for the determination of vitamin D is restricted almost entirely to those used abroad, while no mention is made of the technique adopted by the U. S. Pharmacopeia and the Association of Official Agricultural Chemists, which is standard in the United States for the assay of vitamin D in food and pharmaceutical materials. It is perhaps not so difficult to understand the large amount of space devoted to the discussion of "Vitamin D-Stoss," a method developed and used almost exclusively in Germany for the treatment of rickets with single massive doses (from 200,000 to 600,000 international units) of a crystalline preparation of vitamin D. An example of the type of controversial material frequently included in this book is the discussion of the alleged aphrodisiac effects of vitamin D. This discussion, unfortunately, confuses libido with ovarian function and apparently is not based on adequate knowledge of sexual physiology.

The chief value of the book lies in the detailed reports of the authors' own studies of the toxicity of vitamin D and of their own observations of the effects of massive doses of vitamin D on blood chemistry and on calcium and phosphorus balance.

Observations on a total of 166 subjects are reported, the results of which may be summarized by the statement that the authors claim to have found that, in the recommended dosage of from 200,000 to 300,000 international units a day, immediate "toxication" is relatively rare and readily detected in its early stages. In the studies of calcium and phosphorus metabolism the intake of these minerals was uncontrolled and in the large majority of instances considerably below the standard minimum daily requirement. Also the possible presence or absence of calcium stores was not taken into account in the interpretation of the results. However, the results reported indicate that, in the words of the authors, "there is no conventional picture of mineral metabolism in arthritis and . . . no characteristic response to vitamin D that can be considered in this relation." The authors state further "It is clear . . . that vitamin D does not completely restore the subject to a normal state, probably because it does not generally correct the fundamental disturbance that made the subject susceptible in the first place. Therefore, when the subject reaches the state when no further clinical improvement is apparent, it is useless to continue this treatment. Other measures must then be employed." Nevertheless they insist that vitamin D is of value in relieving the symptoms of arthritis at least temporarily. The objection that the clinical investigations were not adequately controlled and that the relief of symptoms might be due to a remission of the disease has not been satisfactorily met. The book contains a forty-eight page bibliography which is said to contain more than 900 references. It is well printed and contains numerous tables and graphs. This book should be of interest to the physiologist or the physician who may profitably explore the more speculative and controversial phases of our knowledge of vitamin D, but it is not to be recommended as either an authoritative or well balanced review of established knowledge concerning the chemistry or physiology of this vitamin.

It is perhaps not out of place in a review of this sort to point out also that the commercial preparation Ertron, a high vitamin D potency preparation marketed by the Nutrition Research Laboratories, is exploited as a treatment for arthritis in advertising which leans heavily on the work of Dr. Reed and his associates. This preparation has been declared not acceptable by the Council on Pharmacy and Chemistry. Significantly in the prefatory material of the book there occurs acknowledgment of the receipt of financial aid from the Nutrition Research Laboratories. The index shows nine references to the product Ertron.

Actuarial Technique and Financial Organisation of Social Insurance: Compulsory Pension Insurance. By Lucien Féraud. International Labour Office. Studies and Reports Series M (Social Insurance) No. 17. Paper. Price, \$4; 15s. Pp. 568. Washington, D. C. & Geneva: International Labour Office (League of Nations); London: P. S. King & Son, Ltd., 1940.

Only three of the risks that can be covered by social insurance are considered in this volume—those of invalidity, old age and death. The treatment consists of a general introductory discussion followed by monographs on Belgium, Czechoslovakia, France, Great Britain and Italy.

While compulsory sickness insurance is not directly discussed, much of the actuarial and descriptive matter, both of which are very exhaustive, cannot help but be of value to any one concerned with the organization of almost any type of social insurance. The difficulties which hamper actuarial calculations in these fields are pointed out. Because "there have been incessant modifications" in all such systems, and such modifications have been made by legislation or regulation without much regard for actuarial conditions, it is very difficult to lay down rules by which accurate calculations can be made. In the first place there is nearly always a complete lack of statistics "concerning the group that it is proposed to insure . . . the insured group is large, scattered, and constantly liable to variation." Furthermore, "there is no social insurance scheme in existence which has operated without modification long enough to include only persons . . . who have been subject to the same legislation since they were at the lowest age limit for entering insurance." The actuary "must take into account a host of financial, economic, social and even political considerations." It is recognized that insurance itself often produces important effects such as increasing the amount of invalidity.

In addition to many valuable statistical tables concerning the operation of various systems of insurance there are complicated mathematical formulas which are applied in the effort to establish norms for the diverse elements involved in the financial calculations required.

An Atlas of the Commoner Skin Diseases with 120 Plates Reproduced by Direct Colour Photography from the Living Subject. By Henry C. G. Semon, M.A., D.M., F.R.C.P., Physician for Diseases of the Skin, Royal Northern and Hampstead General Hospitals, London. Photography under the direction of Arnold Moritz, B.A., M.D., B.C. Second edition. Cloth. Price, \$12. Pp. 272. Baltimore: William Wood & Company, 1940.

This dermatologic reference book presents in one compact volume, at a reasonable price, 120 Finlay color plates to illustrate the dermatoses most frequently seen in routine practice. Opposite each plate is a short clinical description of the disorder presented, with a practical outline of treatment and an occasional helpful table of differential diagnosis. The various diseases are arranged in convenient alphabetical order. The photography, by Arnold Moritz, is excellent. The illustrations are taken not from moulages but directly from living subjects and they are accurately reproduced to maintain lifelike color values. The cases have been selected intelligently to bring out the cardinal clinical features of each disease, and in the portrayal in color there is a depth or third dimensional effect which is lacking when the illustrations are in the usual black and white. The volume is not intended to be a textbook but rather an accessory aid to the student and practitioner in the detailed study of diseases of the skin. To this end it succeeds admirably and the author, artist and publishers are to be congratulated on the contribution they have made.

Biokhimiya adrenalina. [By] A. M. Uterskiy. [Biochemistry of Adrenalin]. Cloth. Price, 8 rubles. Pp. 302. Kiev: Izdanie Ukrain'skogo Instituta Eksperimental'noy Meditsiny, 1939.

Problems pertaining to the biochemistry of epinephrine did not receive the exhaustive treatment in literature accorded the physiology and the pharmacology of epinephrine. The author points out that, as a hormone and a substance genetically and functionally related to the mediators of the sympathetic nervous system, epinephrine presents a most important and fascinating subject for biochemical investigation. In attempting to present a systematic treatment of the fundamental problems of the biochemistry of epinephrine the author utilizes the accepted theories and hypotheses as well as his own ideas based on the investigations carried out in his laboratory. The volume contains eight chapters dealing with the chemistry, the role of secretion, the various forms in which epinephrine exists in the living organism, epinephrine as a mediator of sympathetic nervous impulses, the chemical nature of sympathenes, the formation of epinephrine, the oxidation products of epinephrine and the role of epinephrine in metabolism and in the dynamics of the hepatic and the muscle cell. The volume is a timely contribution to an important subject. Unfortunately, it does not contain a summary in any of the accessible languages.

A Text-Book of Psychiatry for Students and Practitioners. By D. K. Henderson, M.D., F.R.F.P.S., F.R.C.P.E., Physician-Superintendent of the Royal Edinburgh Hospital for Mental Disorders, Edinburgh, and R. D. Gillespie, M.D., F.R.C.P., D.P.M., Physician for Psychological Medicine, Guy's Hospital, London. Fifth edition. Cloth. Price, \$6. Pp. 660. New York & London: Oxford University Press, 1940.

Five editions of this textbook indicate the established place which it has made for itself in the field that it concerns. The new edition gives a detailed outline of the insulin and metrazol shock techniques. Indeed, the authors point out that these methods in individual instances have accomplished brilliant results, have infused psychiatric treatment with new enthusiasm and have added directly and indirectly to research along clinical, chemical and biochemical lines. Psychiatrists are still concerned with new methods for classification of mental disturbances. New additions have been made to the discussions of heredity and to the play technic for the treatment of nervous children. Also some attention has been added to the considerations of the new trend in the field of psychosomatic medicine. The chapter on epilepsy calls attention to recent investigations with the encephalogram. It is the belief of the authors that the sheet anchor of treatment is bromide, with a useful accessory in phenobarbital. They believe that dilantin sodium is a valuable alternate for phenobarbital.

Trudy instituta im. Gannushkina. Vypusk tretiy. Pod redaktsiyey T. A. Geyera i S. G. Zhislina et al. Vypusk chetvertiy: Psikhiatricheskaya bolnitsa. Pod obshchey redaktsiyey M. Z. Kaplinskogo i S. V. Kravtsova, et al. [Works of Gannushkin Institute for Neuro-Psychiatric Research. Part 3. Part 4: Psychiatric Hospital.] Cloth. Price, 12 rubles, 50 kopeks; 13 rubles. Pp. 312; 326, with illustrations. Moscow, 1939.

Volume III contains papers reporting the work of the institute for the past two years devoted to the subjects of the symptomatology and therapy of schizophrenia. Particularly interesting is the paper by A. C. Kronfeld, in which the author reviews the extensive historical material regarding the concepts of schizophrenia leading up to its formulation by Kraepelin. The convulsive-irritative methods of therapy are described and at the same time emphasis is laid on the need of physical therapeutic measures such as hydrotherapy and electrotherapy.

Volume IV is devoted principally to the problems of organization of a psychiatric hospital and to the problems of the patient after his discharge from the hospital. No particularly new or interesting views are disclosed. The need for accuracy in statistical studies of therapeutic results is emphasized.

A Synopsis of Surgery. By Ernest W. Hey Groves, M.S., M.D., B.Sc., Consulting Surgeon to the Bristol General and Municipal Hospitals, Bristol. Eleventh edition. Cloth. Price, \$5. Pp. 714, with 208 illustrations. Baltimore: William Wood & Company, 1940.

From a purely pedagogic point of view a synopsis may be objectionable if the student relies on it as his sole source of information. While it makes it easier for him to memorize facts for the next examination, it is just as easily forgotten soon after, for the mental process involved in reading a more or less complete text is eliminated. The author with his wide experience as teacher did not from the beginning intend the work to be anything else than a supplement to the major textbooks. As such, this volume may well prove to be of aid to the student in rapidly surveying the entire field. Regarded in this light the volume is easily the best in its class and may be unreservedly recommended to the senior medical student and to the so-called busy practitioner. The popularity of the work is attested by the many editions through which it has passed since its first appearance in 1908.

Voprosy neurorentgenologii. Pod redaktsiyey B. N. Mankorskogo, Ya. I. Geynsmanna. Questions neuro-radiologues. Cloth. Price, 15 rubles. Pp. 266, with illustrations. Kiev: Gosudarstvennoe Meditsinskoe Izdatel'stvo USSR, 1939.

The volume contains some of the more important papers presented at the session of neurorentgenologists of the Kiev Psychoneurologic Institute in 1936. The papers deal with roentgenologic study of the various anatomic questions pertaining to the skull and the spinal dural sac, the various roentgenologic methods such as craniography, myelography and encephalography, and the value of roentgenology in diagnosis and localization of brain tumors. The character of the work as reflected in these papers appears to be abreast of the present day advances in the field. Each paper has a brief summary in French.

A Check List for the Survey of Health and Physical Education Programs in Secondary Schools. By Terry H. Dearborn, School of Hygiene and Physical Education, Stanford University. Paper. Price, 60 cents. Pp. 23, Stanford University, California: Stanford University Press, 1940.

This pamphlet is one of the many appraisal devices which are being used more and more extensively in public health, social service and educational fields. This outline includes eight major divisions, of which the first is a description of the school and community, the second deals with organization and administration of the school health program, the third with hygiene of the school program, the fourth with health supervision, the fifth with hygiene of environment, the sixth with hygiene instruction, the seventh with physical education for boys and the eighth with physical education for girls. Altogether it makes a lengthy questionnaire which would require a considerable study to execute satisfactorily. As with all appraisal instruments, its value is in direct proportion to the percentage of factual information as distinguished from opinions which it contains. Objectivity of self appraisal is difficult of achievement. This questionnaire seems for the most part to be about as objective as could be expected of a questionnaire on a subject involving so many variables and personal equations. In the last analysis, of course, the effectiveness of a program of health and physical education

is not measured by equipment and curriculum but by such intangibles as qualifications of personnel, personality of instructors and resulting instructor-student relationships. Although the instructions state that this check list is not designed to be used as a questionnaire, it nevertheless has all the characteristics of such an instrument and will unquestionably be used as such in many instances.

School Health Problems. By Laurence B. Chenoweth, A.B., M.D., Professor of Hygiene, University of Cincinnati, and Theodore K. Selkirk, A.B., M.D., Instructor in Pediatrics, College of Medicine, University of Cincinnati, Cincinnati, Ohio. With a Chapter on School Health Administration. By Richard Arthur Bolt, M.D., Dr.P.H., Director, Cleveland Child Health Association, Cleveland. Second edition. Cloth. Price, \$3. Pp. 419, with 115 illustrations. New York: F. S. Crofts & Co., 1940.

This book, in its fourth printing, deserves its wide circulation. It is a concise, adequate and comprehensive discussion of school health problems, dealing with history, the laws and factors involving growth in children, physical examination of children and its educational aspects, control of communicable diseases, light and vision, acoustics and hearing, special classes, tuberculosis in school children, mental hygiene, physical education, safety and accident problems, principles and school administration, sanitation and the teaching of health. The book gives scientific fundamentals on which various procedures are based and discusses with eminent objectivity and a due regard for all points of view the various problems which involve controversial or doubtful procedures. One need not necessarily agree with all the opinions of the authors to recognize that this book is based on a broad understanding of the subject, both from experience and from a wide familiarity with the literature. The book is so extensively documented that it would be valuable for its bibliography alone, if for nothing else. It should be of utmost value to school administrator, school nurse, classroom teacher, health supervisor, physical education personnel, school physicians, practicing physicians and members of school boards.

The Calcified Pineal Gland. By Dr. W. Bergmann. Paper. Pp. 89, with 15 illustrations. Assen: Van Gorcum & Comp. N. V., 1940.

This superficial, uncritical monograph is not worth critical consideration.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Liability for Excessive Reaction of Patient to Mercury Oxycyanide.—The plaintiff, who was afflicted with an incipient cataract of her right eye, and a friend, Mrs. Carver, who apparently had a similar affliction, on Sept. 9, 1937, went to the clinic operated by Drs. McLaughlin and Nauth, Dr. Walter, an eye specialist employed by the clinic, injected under the conjunctiva of the plaintiff's right eye 5 drops of a solution which had been prepared by the clinic's pharmacist, composed of 1 part of mercury oxycyanide in 10,000 parts of distilled water. He also injected some of the same solution into Mrs. Carver's eyes. The purpose of the injection was to set up an irritation to stimulate circulation in the eye and thereby arrest the cataract. An excessive reaction to the drug occurred in the plaintiff's right eye and a chronic inflammation of that eye resulted. Dr. Walter treated her for this condition until she went elsewhere for treatment. The plaintiff later sued all three physicians for malpractice and recovered a verdict in her favor. From the judgment of the trial court denying their motion for a judgment notwithstanding the verdict or for a new trial, the defendants appealed to the Supreme Court of Minnesota.

At the trial defendant Walker admitted that the reaction in the plaintiff's right eye was greater than anticipated or usual. He testified that he had made twenty injections into the eyes of different patients, using the same solution as he had injected into the plaintiff's eye, without any untoward results except as to the plaintiff, Mrs. Carver and a Mrs. Hays. However, the

excessive reactions in the plaintiff's and Mrs. Carver's eyes were not observed by him until seven days after the injections were made on September 9, and it was not shown whether he observed the excessive reaction in Mrs. Hays' eyes before or after that date. He further testified, and in this he was corroborated by medical experts called by both the plaintiff and the defendants, that injection of a 1:10,000 solution of mercury oxycyanide in the treatment of incipient cataract is good standard practice among eye specialists. The medical testimony also showed that injection of such a solution in a dosage up to 15 or 20 drops is considered safe. Three medical witnesses for the defendants, eye specialists, testified that the unexpected excessive reaction in the plaintiff's eye resulted either from some focal infection in her body or from her supersensitivity to the drug.

The fact that injection of the drug caused an excessive reaction or a bad result, said the Supreme Court, was not proof that either defendant Walker or the clinic's pharmacist was negligent. Common experience teaches that whether a drug is taken internally or is injected into the tissues or the blood stream the reaction is not the same in all persons even of the same age or apparently with the same condition, and the reaction varies greatly at times even as to the same person, depending on his physical or mental condition. Here the evidence was undisputed that "a dose of more than three times that used would be safe." There was no suggestion that defendant Walker's treatment after he discovered the excessive irritation was improper. Although the irritation or inflammation of the plaintiff's right eye did originate or start from the injection made by Dr. Walker, that fact did not prove or tend to prove negligence on his part. On the contrary, all the medical witnesses agreed that starting an irritation in the eye to stimulate circulation is the standard practice in the treatment of incipient cataract. What caused the inflammation to persist was unknown even to the medical experts. The plaintiff's only medical witness ventured no opinion that attributed the prolonged persistence of the irritation to any fault, lack of skill, or negligence on the part of any of the defendants. In the judgment of the court, the record in the case was barren of proof that the protracted irritation or inflammation of the plaintiff's right eye was due to the negligence of any of the defendants. The court concluded that the verdict in favor of the plaintiff was not sustained by the evidence because it was based on mere conjecture or guess. As the court did not believe this a proper case in which to order judgment notwithstanding the verdict, it reversed the judgment of the trial court with direction that a new trial be granted.—*Cassidy v. McLaughlin et al. (Minn.)*, 285 N. W. 889.

Medical Practice Acts: Validity of Revocation Proceedings When Accused Physician Is Incarcerated Out of the State.—In the two decisions reported here the Supreme Court of Florida, in effect, ordered the state board of medical examiners of Florida to rescind and revoke orders previously entered by it at separate times revoking the licenses of two physicians, Weathers and Munch, to practice medicine. At the time of the revocation proceedings both physicians were incarcerated in the federal penitentiary at Atlanta, Ga., after conviction of felonies—Weathers, for a violation of the Harrison Narcotic Act and Munch for illegal use of the United States mails to defraud in selling bogus diplomas and licenses to practice medicine. Prior to holding the revocation proceedings in question notice of the hearings and copies of the charges preferred against each physician were duly served on each of them by registered mail. However, since the appropriate section of the Florida medical practice act in force at the time of each revocation proceeding conferred on the accused physician the right at the hearing to cross examine the witnesses against him, to produce witnesses in his defense and to appear personally or by counsel, the Supreme Court was of the opinion that the orders entered by the board were void as a denial of due process of law. The medical practice act, said the court, contemplates that a hearing on a revocation matter shall be held in the presence of the accused physician. While an accused physician may voluntarily waive that right he cannot be held to have

waived it by his failure to appear when he is powerless to attend because of incarceration in prison, when that fact is known to the board, and when he does no affirmative act constituting a waiver. While the Supreme Court, in effect, restored to the two physicians their licenses to practice in Florida, it stated that nothing in its decisions nor in the prior revocation proceedings would preclude the board in the future from instituting "in a constitutional manner" proceedings looking toward the revocation of Weathers' and Munch's licenses for the commission of the very acts which formed the basis of their conviction in the federal court and for which they served time in the federal penitentiary.—*State ex rel. Weathers v. Davis et al. (Fla.)*, 196 So. 487; *State ex rel. Munch v. Davis et al. (Fla.)*, 196 So. 491.

Medical Services Necessities of Life.—In the opinion of the appellate department, superior court, Los Angeles County, Calif., medical services are necessities of life within the meaning of a California statute (Code of Civil Procedure, section 690.11), which provides that when a judgment is based on a necessity of life the judgment creditor may execute on up to one half of all wages earned by the judgment debtor.—*Medical Finance Ass'n v. Short (Calif.)*, 92 P. (2d) 961.

Society Proceedings

COMING MEETINGS

- American Academy of Ophthalmology and Oto-Laryngology, Cleveland, Oct. 6-11. Dr. William P. Wherry, 107 South 17th St., Omaha, Secretary.
- American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Excelsior Springs, Mo., Sept. 26-28. Dr. James R. Bloss, 418 Eleventh St., Huntington, W. Va., Secretary.
- American Association of Railway Surgeons, Chicago, Sept. 16-18. Dr. Daniel B. Moss, 547 West Jackson Blvd., Chicago, Secretary.
- American Clinical and Climatological Association, White Sulphur Springs, W. Va., Oct. 28-30. Dr. Francis M. Rackemann, 263 Beacon St., Boston, Secretary.
- American College of Surgeons, Chicago, Oct. 21-25. Dr. Frederic A. Besley, 40 East Erie St., Chicago, Secretary.
- American Hospital Association, Boston, Sept. 16-20. Dr. Bert W. Caldwell, 18 East Division St., Chicago, Executive Secretary.
- American Public Health Association, Detroit, Oct. 8-11. Dr. Reginald M. Atwater, 50 West 50th St., New York, Executive Secretary.
- American Roentgen Ray Society, Boston, Oct. 1-4. Dr. Carleton B. Peirce, Royal Victoria Hospital, Montreal, Canada, Secretary.
- American Society of Anesthetists, New York, Oct. 10. Dr. Paul M. Wood, 745 Fifth Avenue, New York, Secretary.
- Association of Military Surgeons of the United States, Cleveland, Oct. 10-12. Dr. H. L. Gilchrist, Army Medical Museum, Washington, D. C., Secretary.
- Central Society for Clinical Research, Chicago, Nov. 1-2. Dr. Carl V. Moore, Washington University School of Medicine, St. Louis, Secretary.
- Clinical Orthopaedic Society, Milwaukee and Madison, Wis., Oct. 18-19. Dr. Myron O. Henry, 825 Nicollet Ave., Minneapolis, Secretary.
- Colorado State Medical Society, Glenwood Springs, Sept. 11-14. Mr. Harvey T. Sethman, 537 Republic Bldg., Denver, Executive Secretary.
- Delaware Medical Society of, Rehoboth Beach, Sept. 9-11. Dr. C. L. Munson, 1015 Washington St., Wilmington, Secretary.
- District of Columbia Medical Society of the, Washington, Oct. 15-17. Mr. Theodore Wiprud, 1718 M St., N.W., Washington, Secretary.
- Idaho State Medical Association, Sun Valley, Sept. 11-14. Dr. J. N. Davis, 204 Fourth Ave., East, Twin Falls, Secretary.
- Indiana State Medical Association, French Lick, Oct. 29-31. Mr. Thomas A. Hendricks, 23 East Ohio St., Indianapolis, Executive Secretary.
- Inter-State Postgraduate Medical Association of North America, Cleveland, Oct. 14-18. Dr. W. B. Peck, 27 East Stephenson St., Freeport, Ill., Managing Director.
- Kentucky State Medical Association, Lexington, Sept. 16-19. Dr. A. T. McCormack, 620 South Third St., Louisville, Secretary.
- Michigan State Medical Society, Detroit, Sept. 24-27. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing, Secretary.
- Mississippi Valley Medical Society, Rock Island, Ill., Sept. 25-27. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.
- Nevada State Medical Association, Las Vegas, Oct. 11-12. Dr. Morace J. Brown, 120 North Virginia St., Reno, Secretary.
- Omaha Mid-West Clinical Society, Omaha, Oct. 28-Nov. 1. Dr. J. D. McCarthy, 107 South 17th St., Omaha, Secretary.
- Pacific Association of Railway Surgeons, Reno, Nev., Sept. 20-21. Dr. W. T. Cummins, 1400 Fell St., San Francisco, Secretary.
- Pennsylvania Medical Society of the State of, Philadelphia, Sept. 30. Oct. 3. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh, Secretary.
- Southern Minnesota Medical Association, Red Wing, Sept. 23. Dr. Harold C. Habein, 102 Second Ave., Rochester, Secretary.
- Vermont State Medical Society, Rutland, Oct. 9-10. Dr. B. F. Cook, 154 Bellevue Ave., Rutland, Secretary.
- Wisconsin State Medical Society of, Milwaukee, Sept. 18-20. Mr. J. G. Crownhart, 110 East Main St., Madison, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama State Medical Assn. Journal, Montgomery

10:1-40 (July) 1940

- Vitamin Deficiencies in Practice. J. B. Youmans, Nashville, Tenn.—p. 1.
History of Ether Anesthesia: Its True Discoverer. S. A. Gordon, Marion.—p. 7.
The Government's Aid-to-the-Blind Program. B. F. Jackson, Montgomery.—p. 9.

*Incidence of Trichinosis Among County Hospital Patients in Detroit Area: Based on 500 Consecutive Autopsies. S. E. Gould, Eloise, Mich.—p. 431.
Unusual Spirochete Recovered from Blood in Arthritis. Thelma Wenzel, Nashville, Tenn.—p. 460.
Rheumatic Heart Disease: Analysis of 110 Cases. A. Levitt and S. J. Jaskiewicz, Buffalo.—p. 467.
*Sputum Studies in Pneumonia as Aid in Prognosis. A. W. Frisch, Detroit.—p. 472.
Tubercular Sclerosis with Cerebellar Involvement. A. F. Liber, New York.—p. 483.
Clinical Blood Cultures: Analysis of Over 5,000 Cases. H. Fox and J. S. Forrester, Philadelphia.—p. 493.

Incidence of Trichinosis in Detroit Area.—Gould investigated the incidence of trichinosis in 500 unselected consecutive necropsies of county hospital patients in the Detroit area and discovered ninety-three positive cases of infestation of *Trichinella spiralis*. The first ninety cases were examined by the digestion method only and eleven positive cases (12.2 per cent) were found. In the remaining 410 cases the pectoral muscle and diaphragm were examined by the microscopic press method and the Baermann digestion technic and eighty-two positive cases were found, an incidence of 20 per cent. If the diaphragm alone was available for examination, the highest percentage of positive observations would be obtained by a combined microscopic press examination of a specimen from the tendinous portion along with the examination of a liberal specimen by the digestion technic. An increasing frequency of infestation was found in successive decades from the fourth to the eighth inclusive. High incidences were found for the groups born in Austria, Hungary, Rumania or Bohemia. These were grouped together because it was believed that their food habits, particularly with reference to the preparation of pork products, were similar. In the group of foreign born patients it appeared likely that many had developed their infestation prior to their entrance into the United States. With advancing age there was an increase in the number of cases with calcified cysts. In cases positive on microscopic examination the diaphragms showed an average infestation 2.2 times as great as that of the pectoral muscle specimens. With the digestion technic only 22 per cent of the larvae estimated present in the diaphragm specimens and approximately 63 per cent of the larvae estimated present in the pectoral muscle specimens were recovered in the sediment. In six cases in which all of the digesting fluid was examined fractionally the total number of larvae recovered in each case approximated the number estimated to be present on the basis of the microscopic examination. In thirty-five cases in which *Trichinella* was recovered in the pectoral muscle or diaphragm the heart muscle was examined by the microscopic press and the digestion methods and in none of these cases was a single cyst or larva found. In none of the ninety-three patients with

trichinosis was the disease recognized clinically. Three of the patients gave a history of "rheumatic" symptoms and at necropsy showed no lesion other than trichinosis. A fourth patient with a moderately severe infestation had a clinical diagnosis of alcoholic polyneuritis. It is likely that in the near future an increasing number of clinical and subclinical cases of trichinosis will be recognized during life.

Sputum Studies in Pneumonia as Aid in Prognosis.

In a preliminary report of seventy-eight roentgenographically proved cases of pneumonia a correlation was noted between multiple lobe involvement, decreased circulating leukocytes, incidence of blood stream invasion, mortality and the number of extracellular encapsulated pneumococci in rusty or bloody sputum. The present communication, based on 228 cases, is a continuation of the study. Frisch states that the microscopic examination of rusty sputum is a relatively quick and simple method of differentiating the severe from the mild pneumococcal pneumonias. There is a significant correlation between the number of pneumococci per field in the sputum and the incidence of bacteremia, leukopenia, multiple lobe involvement and the mortality rate. In a group of 181 patients, prognoses based on sputum counts have proved accurate enough to be applicable in individual cases. In addition, preliminary observations on necropsy material tend to support the concept that the number of pneumococci in rusty sputum is a reflection of the number present in some pneumonic areas of the lung. On the basis of these observations it may be possible to classify many cases of pneumonia on admission to the hospital into those requiring vigorous therapy and those which will respond to minimal treatment. Unfortunately some patients do not produce rusty sputum and are not suitable for study. The atypical behavior of type III pneumonia has been observed by numerous investigators. Type III pneumococci have the largest capsule and accordingly produce the greatest amount of specific soluble carbohydrate. The pneumonia induced by this organism is characterized by a predilection for the aged, a prolonged clinical course and a relatively low bacteremic incidence. The response to serum is often unsatisfactory and the mortality rate in bacteremic cases is unusually high. In sputum the type III pneumococcus differs from all others thus far observed in that the number of pneumococci per field does not appear to be closely related to the outcome of the pneumonia.

Follicular Lymphoblastoma.—According to Baggenstoss and Heck, a clinical and pathologic entity variously called "giant follicle hyperplasia of lymph nodes and spleen," "giant follicular lymphadenopathy" and "follicular lymphoblastoma" has been

described in the literature in recent years with increasing frequency. The authors review cases reported in the literature and present a clinical and pathologic study of thirteen cases seen at the Mayo Clinic. Seven of the latter died. In three cases necropsy was performed; in eight the lymph nodes and in two both lymph nodes and spleen were available for microscopic examination. Follicular lymphoblastoma is characterized by an insidious onset with regional or general lymphadenopathy, splenomegaly, absence of anemia or abnormal cells in the blood and by great radiosensitivity of the lesions. The average duration of life after the appearance of the disease is 4.5 years, but two patients have lived as long as seventeen years. The characteristic histologic changes occurring early in the disease consist of an increase in the number and size of the follicles of the lymph nodes and of the malpighian corpuscles of the spleen. There is a tendency toward fusion of the follicles, and the lymphatic sinuses are generally narrowed or obliterated. There is a superficial resemblance between the microscopic appearance of follicular lymphoblastoma and the microscopic appearance of hypertrophy of the secondary centers of lymph nodes resulting from toxic or inflammatory conditions. The histologic criteria which enable the histopathologist to distinguish the two conditions are outlined in a table. In certain rare instances in which the microscopic appearance is not typical of either follicular lymphoblastoma or inflammation it may be wise to reserve diagnosis and to use a descriptive, noncommittal term, such as "follicular hypertrophy." Subsequent observation and biopsy frequently will bear out the suspicion that the condition is an early instance of follicular lymphoblastoma.

Gastroscopic Observations in Duodenal Ulcer.—Christiansen stresses the disagreement between the gastroscopic and the pathologic-anatomic concepts of the pathogenesis of peptic ulcer. Konjetzny maintains that chronic ulcer is the end product of a primary chronic gastroduodenitis which passes through the catarrhal and the erosive stage, reaching its climax in the ulcerative stage with the formation of one or more chronic ulcers. In contrast to this view, Schindler and other gastroscopists consider chronic peptic ulcer and gastritis as two different lesions without causal connection. Gastroscopy in most cases of chronic ulcer does not reveal gastritis. Gastritic alterations which may appear in cases in which the ulcer gives rise to retention of stomach contents are secondary and curable. Ulcerations may appear in primary gastritis but they do not develop into chronic ulcers, since they are acute and transitory phenomena. Christiansen found seventy cases of roentgenologically verified duodenal ulcer among more than 500 patients with organic lesions of the digestive tract. In none of these was it practicable to ascertain by relief examination changes in the stomach. The patients were examined gastroscopically at a time when they had pronounced dyspeptic symptoms and prior to the institution of treatment. Most of them were submitted to gastroscopic examination several times. He found that, regardless of the secretory conditions, gastroscopy demonstrated definite changes in the mucous membrane in forty-nine of the seventy cases (70 per cent) while the gastroscopic aspects were normal in twenty-one (30 per cent). Thus, in contrast to Schindler's opinion, the gastroscopic examination revealed that the stomach in the majority of the cases was the site of pronounced pathologic alterations. The frequency of gastritis in duodenal ulcer cannot, however, be taken to confirm the observations of Konjetzny, as there is a considerable difference between the changes observed and those found in resected specimens. The author reviews a case history which furnishes an explanation of the divergence between Konjetzny and Schindler. If resection had been performed on a patient when his illness was at its worst, the specimen would have presented the picture on which Konjetzny based his theory. There would have been a duodenal ulcer associated with a violent, erosive, antral gastritis. The course of the disease showed, however, that these pronounced changes were of an acute character, healing within a few weeks when the pyloric spasm subsided and the retention disappeared. Improvement of clinical symptoms ran parallel with rapid healing of severe gastric changes, while the roentgenographic changes in the duodenum remained constant. This may be interpreted as indicating that the particular duodenal ulcer is the primary lesion while gastritis is secondary. The author thinks that, as a general rule,

patients with a nonstenotic duodenal ulcer are liable to pathologic changes in the gastric mucosa even though no abnormality may be demonstrated by roentgenography or the Ewald test meal. Gastroscopy is the method of examination capable of settling this question. The gastritis may be total or partial. The erosions are acute manifestations which may heal in a few days, regardless of whether the gastritis improves at the same time. Transition to a chronic gastric ulcer has not been observed. The typical ulcer symptoms seem to appear in cases in which the stomach is affected. Acute gastric retention may be associated with severe erosive changes in the stomach. These changes are inconstant and may disappear rapidly when the retention subsides. Probably this condition does not involve a primary gastritis, as has been claimed by Konjetzny, but more likely secondary peptic injury, as asserted by Schindler.

Variability of Blood p_{H_2} and Meteorologic Factors.

Berg and his associates studied the variations in the blood p_{H_2} during one year in a group of "normal" dogs and compared them with similar determinations made on human beings. They found a high statistical correlation in comparing the continuous p_{H_2} values in dogs with those of human beings. A relatively wide degree of fluctuation was observed in both. In man the weekly averages varied from 7.28 to 7.68, while in dogs they varied from 7.32 to 7.68. In comparing the blood p_{H_2} and the weather, statistically significant coefficients were found with barometric pressure and temperature, with a distinctly higher correlation for barometric pressure than for temperature. Increases in p_{H_2} were associated with increases in barometric pressure. However, the relationship between p_{H_2} and tempera-

ture was not as marked and only at higher temperatures were increases in p_H definitely associated with increases in temperature. Varying results were found in attempting to evaluate seasonal influences. Failure to duplicate seasonal results is logical, for one spring may not be like another spring and one May not like another May. The temperature may be low and the barometric pressure high, or they may be unstable one year and more stable the next. One cannot compare corresponding months of different years and consider them similar only because of their order in time. On such a basis failures to duplicate results cannot be considered as discounting climatic influence.

Sulfanilamide for Venereal Lymphogranuloma.—Stein used sulfanilamide in the treatment of thirty-five cases of the bubonic type of venereal lymphogranuloma. The duration of the disease in thirty-two cases varied from two days to three months, and in one each it was one, two and three years respectively. All the acute cases cleared up clinically with the same relative speed, but in the cases of longer duration in which fibrosis had occurred the course was different. The dosage of sulfanilamide varied from 4 to 5.3 Gm. divided into four daily doses. Most of the patients were not hospitalized but returned to the clinic three times a week. The amount of the drug given was carefully calculated to last until the next clinic visit. Patients were not informed as to the nature of the medication; thus if the patient experienced toxic symptoms but did not return, no great harm could have occurred. Few toxic effects were encountered. About 50 per cent of the patients complained of headache, dizziness or other minor symptoms. In no case was it considered necessary to stop medication. Of the thirty-five patients treated, the results of three are unknown. The remaining patients were cured, with complete subsidence of the local lesions and relief of all constitutional symptoms. In from two

to ten days the patients felt better and had no further pain. In from five days to four and one half weeks all the lesions had healed, excluding the two cases with draining sinuses, which required about three months of treatment. Two patients with elephantiasis improved within two weeks. Of twenty-two patients treated between six and eight months ago twenty could be followed up and nineteen are clinically well today. All constitutional symptoms have disappeared. The twentieth patient took sulfanilamide for only two days. Subsequently the gland enlarged and ruptured. A draining sinus was established, and the patient was confined to bed for about ten days. Finally the lesion healed. It seems necessary to continue therapy for from seven to ten days after the lesions have completely subsided. In the ordinary case this amounts to about four weeks of treatment with 4 Gm. a day, three weeks with 5.3 Gm. a day or two weeks with 6.6 Gm. a day.

Etiologic and Pathologic Factors in Intestinal Cancer.

—David calls attention to the frequency of supposedly benign polypoid growths of the large intestine and their relation to cancer. His studies comprised 200 resected cancers and 100 specimens of supposedly benign polyps of the colon and rectum. One of the most common alterations in the mucosa of the colon is the occurrence of millet seed-sized flat elevations, which are usually multiple and occur mostly in old persons. The histologic structure of these lesions is one of simple hyperplasia with inflammation or lymphatic hyperplasia of the submucosa. In exceptional instances the lesion may resemble larger polyps, which are almost certainly tumors rather than simple hyperplasia. The next most frequently seen type of polyp is the adenomatous polyp. It varies in size from that of a pea to that of a large cherry and may be transparent or of the same color as the mucosa. It has the indications of being a benign lesion. Other polyps of this adenomatous group present evidence of a growth or tumor change in their epithelium; their color is plum or cherry. They may become large, with a cauliflower surface, and contain branching stalks of connective tissue. In this type of adenoma the mucosa has taken on real growth propensities; it is a benign tumor. Another gross division of benign polypoid tumors is that of papilloma or villous tumors. The tendency to wild, disorganized tissue growth is found in these tumors, and in two of twenty-seven cases the author has seen an early carcinoma beginning in the lesion. One of the most convincing arguments in favor of the relation of polyps of the large bowel

to the development of carcinoma is seen in multiple polyposis, in which the entire colon and rectum may be studded. The etiologic basis here is a hereditary one. They have a tendency to malignant degeneration. Akin to this lesion, but lacking the hereditary factor and the extensive involvement, is the occurrence of multiple polyps. It seems probable that the malignant degeneration of these polyps is responsible for the increasing recognition of multiple cancers of the large intestine. The author observed five double cancers of the large intestine, in four of which the condition was highly suggestive of carcinomatous degeneration of polyps. Of less importance are the so-called lymphoid polyps, which may appear as multiple slightly elevated flat lesions a few millimeters in diameter, affecting the colon and rectum, and really a form of lymphoid hyperplasia. Of more clinical interest but lacking carcinomatous tendencies are the large lymph polyps, of which the author has seen five instances in the rectum. The last classification is the inflammatory type. The elevations and tumor-like growths on the mucosa of a patient with this type of polyp ranged from simple hyperplasia to typical adenoma formation. The author concludes that there is a gross and gradual histologic transition in the mucosa of the large bowel from hyperplasia to adenoma or from papilloma to carcinoma. Whether the tendency to carcinoma is present from the start is not known. Carcinomatous changes can be diagnosed only by gross evidence of induration or ulceration and by microscopic evidence of invasion. While many of the polyps of the colon remain benign for years, they cannot be trusted to do so and should be thoroughly removed, locally if benign, and radically if malignant. The results of biopsy are not conclusive unless the material is taken from an area of ulceration or induration. It is frequently impossible to make a diagnosis of malignancy from a small piece of tissue. It is better to examine the whole tumor. The earliest carcinomas the author has seen in the large intestine were 1 to 2 mm. ulcerating lesions found on polyps.

Intrathecal Administration of Tetanus Antitoxin.—Fior records experiments which show that the intracisternal injection of antitoxin into dogs suffering from early mild or moderately severe tetanus yields far better results than intravenous injection. The experiments in themselves do not warrant the use of intracisternal injections for patients, but when considered with the clinical reports of Yodh or Vener they furnish a strong argument for the employment of this form of treatment. It is highly desirable that a more refined antitetanic serum be produced in order to minimize the severe reactions described by Dietrich. This may be accomplished in one of two ways. First, ordinary antitetanic horse serum may be concentrated and purified by the action of proteolytic enzymes, as has been done with diphtheria antitoxin. Secondly, human serum containing a high titer of tetanus antitoxin may be produced by active immunization of human donors with tetanus toxoid. This possibility was first suggested by Hyland of Los Angeles. The reported experiments comparing the efficacy of intracisternal and lumbar routes are suggestive but not conclusive. Had the animals been kept in a position to cause a gravitational flow of the serum to the medulla, the apparent difference in results with the two sites of injection might have disappeared. Similarly, the author does not consider that his experiment, which was designed to evaluate the importance of the inflammatory reaction to foreign serum in the meninges, is conclusive. Additional studies with purified serum on a larger number of animals are necessary before this question can be settled.

Gas Gangrene: Wool as Source of Contamination.—Maes observed that contamination with woolen clothing is a common source of infection in cases of gas gangrene. At his suggestion Gage had studied samples of clean wool and was able to grow spore-bearing organisms in practically all instances. Given a favorable type of wound (muscle injury) and contamination with wool clothing, the ideal conditions exist for the development of gas bacillus infection. With the assistance of Williams, Maes analyzed the seventy-three cases of gas gangrene observed at the Charity Hospital of New Orleans during the ten year period from 1930 to 1939. He investigated the seasonal incidence because he believed that the wool clothing worn in the cooler months is an important source of contamination. He

found that there was a higher incidence during the cool months. Schenken made cultures of sample of new wool and found gram-positive spore-bearing anaerobic gas-forming bacilli, morphologically compatible with the members of the Clostridium group in eleven out of twelve samples. Dry cleaning and steam pressing did not materially alter the incidence of the organism. Gas bacilli were not found in any of the twelve samples of the material which did not contain wool. This confirms the fact that contamination with clean wool in certain types of wounds should be considered a precursor of gas gangrene. The author observed two instances in which gas bacillus infection followed hypodermic injections. In each of these instances wool blankets had been in contact with the skin or with a raw surface. Thus contamination with any woolen article, even clean clothing, makes rigid prophylactic measures imperative. It is urged that physicians suspect anaerobic infection with production of gas gangrene whenever wounds of the extremities involving muscle have been contaminated with wool or with soil. Such wounds should be treated by wide incision or by thorough débridement. Prophylactic administration of the specific serum seems to be of value, and from the report of Keating and Davis the prophylactic use of roentgen therapy is justified. In the presence of suggestive signs of such infection, specific treatment should be started at once. Since there is some benefit from the anti-gas bacillus serum and from sulfanilamide and since there is positive evidence of benefit from the use of the roentgen rays, all three should be used. Wide incision and amputation still have their place and must be used when conditions warrant.

Vitamin A in Rheumatoid Arthritis.—Hall and his associates compared the distribution of vitamin A values among seventy-nine patients with rheumatoid arthritis with those of thirteen normal individuals on a similar dietary regimen. Information was sought as to the daily requirement of vitamin A and the effect, if any, on the course of the disease when this requirement was fulfilled. The average initial biophotometer reading of the seventy-nine patients was 0.78 and that of the controls 0.32 millifoot candle. Twenty-eight patients had initial readings at or below the normal limit of 0.5 millifoot candle, and twenty-eight had initial readings between 0.5 and 1 millifoot candle and were considered borderline or subnormal. The reading of seventeen fell between 1 and 1.5 millifoot candles. This was considered to indicate moderate vitamin A deficiency. The remaining six patients had initial readings greater than 1.5 millifoot candles and were considered severely deficient in vitamin A. The older age groups had more abnormal initial biophotometer readings. However, when the dark adaptation values of arthritic patients between the ages of 20 and 29 are compared with those of controls of the same age, they are seen to be definitely abnormal. The 30 per cent of the patients who were moderately or severely deficient showed no obvious clinical manifestations of vitamin A deficiency, xerophthalmia or keratomalacia. Night blindness was noticed by only one of the patients. During the test, several patients complained of nyctalopia. The provision of adequate vitamin A therapy effected no clinically observable favorable result in the rheumatoid patients, but it would seem desirable to eliminate an existing deficiency of this vitamin as a general supportive measure. In rheumatoid arthritis, as in other chronic or infectious diseases, there is an increased demand for vitamin A as measured by the dark adaptation curve. Many arthritic patients require from four to ten times the amount of vitamin A present in their regular diet to maintain normal dark adaptation curves. At present it is not known whether this increased need represents an increased utilization, decreased absorption or an inactivation of the vitamin.

*Chigger Mites.—p. 1312.

Isolation of Micro-Organism in Dandruff.—According to Emmons, a small yeastlike micro-organism is almost always associated with the dry or greasy scales of seborrhea capitis or dandruff. It can be found on the majority of "normal" scalps and is present on other skin surfaces. This micro-organism is known as the "bottle bacillus" and *Pityrosporum ovale*. Although observers agree that *Pityrosporum ovale* is usually found associated with seborrhea, they do not agree on its cultural characteristics or its etiologic significance. Many investigators have tried in vain to isolate this fungus. In most cases when *Pityrosporum ovale* has been isolated, assuming that the micro-organism obtained was correctly identified, the isolations were largely fortuitous, most attempted cultures yielding no growth or only contaminants. The author reports a method of isolating *Pityrosporum ovale* which is dependable. *Pityrosporum ovale* was repeatedly and easily isolated by planting scales from

seborrhea oleosa in acid dextrose broth containing from 23 to 44 per cent glycerin and incubating at from 30 to 37 C. Subcultures were successfully carried on mediums prepared by pipetting off ether extract of hydrous wool fat, oleic acid or seborrheic scales over agar slants, as described by Benham. Evidence that the organism was actually *Pityrosporum ovale* was furnished by the necessity for using special mediums, the resemblance of the fungus in culture and in the skin, and a series of observations of the inoculum which showed a continuity of development of the cells of *Pityrosporum ovale* in the scales. Attempts were made to determine whether *Pityrosporum ovale* is pathogenic. Instead of trying to find and experimentally infect an individual who did not already carry the fungus, it was decided to inoculate a seborrheic individual and to measure any noticeable increase in the time required to develop seborrhea in the area inoculated as compared with an uninoculated area. Lesions of seborrhea did not appear any sooner in the inoculated areas than in the control areas. These experiments were repeated, but no pathogenic properties of the fungus could be demonstrated. Although some features of seborrhea seem consistent with a parasitic etiology, the failure of these inoculations would give support to the contention of many dermatologists and mycologists that *Pityrosporum ovale* is a saprophyte especially adapted to growth on the skin but without etiologic significance in seborrhea.

Chigger Mites.—Chiggers have a widespread distribution in the United States. They have been found in low lands and well up in the mountains wherever there is a rough growth of weeds and shrubbery. They may be encountered from the latter part of April until the last of October, depending on conditions of temperature and moisture. Chiggers attach themselves to the surface of the skin by means of their mouthparts and feed much as do ticks. They apparently feed on epidermal tissue liquefied by a secretion which they themselves inject into the skin. When they become fully engorged they drop off. The localization of chigger attachment is determined by two factors, the tightness of the clothing at certain parts of the body and the thickness of the skin. Experiments have shown that chiggers attack by preference where the skin is very thin and the flesh wrinkled or tender. Because of their size, 150 microns in width before they have become engorged, chiggers are unable to enter the pores of the skin (which range from 20 to 50 microns in diameter), but they frequently attach themselves at the mouth of hair follicles. Although it is widely believed that chiggers burrow into the skin and embed their entire body, this method of attack must be extremely uncommon. An intense itching develops within the first twenty-four hours after exposure, and this is followed by a breaking out of wheals or papules surrounded by an inflamed area. If the lesions are numerous, fever, headache and temporary nervous upset may result. If there has been exposure to chiggers, an application of kerosene or 95 per cent alcohol will kill the larvae. As soon as possible after exposure, a thick lather of soap should be applied to the affected parts and allowed to remain for ten minutes or more before bathing. Even though the larvae may be removed or killed soon after attachment, usually enough secretion has been introduced to cause the characteristic itching lesion, which may be temporarily relieved by ammonia or strong salt water, or a mild mercurous chloride-phenol lotion. Collodion with metaphen applied to the lesions is recommended both to relieve the itching and to prevent infection. An efficacious measure to prevent attack by chiggers is the liberal sprinkling of the stockings and underclothing with sublimed sulfur. Some authors state that spraying of the shoes, stockings and trouser legs with one of the proprietary fly-repellant preparations is successful in warding off attacks by chiggers.

Amyotonia Congenita and Congenital Myopathy.—

Turner believes that the relationship between congenital amyotonia and the myopathies has been somewhat clarified by the study of a family which has been under observation at the National Hospital for a number of years. The family consists of thirteen children, six of whom have been affected by the disease. Neither parent was affected. The clinical picture presented by the children in early infancy was typical of congenital amyotonia as described by Oppenheim, from the observations that fetal movements were feeble and appeared late. From the limpness and small size of the children at birth and during the first few weeks of life, it seems probable that the disease was present before birth. The abnormality of fetal movements has been described previously. In early adult life the clinical picture presented by the same patients was equally typical of a myopathy of somewhat unusual distribution, and the course of the disease shows that there was a gradual transition from the state of amyotonia with its marked flaccidity and absence of local muscular atrophy to the state of myopathy with considerable local muscular atrophy and absence of flaccidity. There can be little doubt that the patients were suffering from one disease process, a myopathy, and from this the author concludes that they were affected by a congenital myopathy, which in its early stages had produced the clinical picture of congenital amyotonia. The clinical picture of congenital amyotonia may be produced by a congenital myopathy or by a spinal disorder which is related to the Werdnig-Hoffmann disease.

Reactions from Transfusion of Preserved Blood.—

DeGowin and Hardin report on the 1,604 blood transfusions supervised by the staff of the blood transfusion laboratory from Oct. 11, 1938, until Jan. 19, 1940. The amount of blood transfused varied from 50 cc. for infants to 500 cc. for adults. The total volume of fluid for 500 cc. of citrated blood was 600 cc. The dextrose-citrate mixture (a modification of the Rous and Turner mixture) constituted a total volume of 1,250 cc. when 500 cc. of blood was used. Many recipients received more than one transfusion. The indications for transfusion were chiefly anemia, serum protein deficiency, infections and shock. *In 146 instances the blood was administered within two hours after its collection, considered fresh blood transfusions. The other 1,458 transfusions were done with blood from one to thirty-eight days old. Reactions distinctive of preserved blood were not encountered. The incidence of the various types of reaction did not increase or decrease with the period of storage of the blood mixtures. A limit of ten days of storage at from 3 to 5 C. was found to be safe for citrated blood. Blood stored in the dextrose-citrate mixture was found to be safe for transfusion after thirty days of storage. A comparison of the incidence of pyrogenic

reactions in 951 blood transfusions with that of 7,181 parenteral injections of saline or dextrose solution showed that about 3 per cent of the febrile reactions from the blood transfusions could not be attributed to pyrogens in the apparatus or fluids used. This comparison did not exclude the possibility of the introduction of pyrogenic organisms at the time of the collection of the blood. The presence of pyrogens should be suspected when the incidence of febrile reactions is high. There were two deaths from transfusions—one from incompatible blood and one from cardiac embarrassment. Neither of these could be attributed to the use of preserved blood in contradistinction to fresh blood.

Chemotherapy of Gonorrhea in Women and Children.

—Moffett observed the efficacy of sulfapyridine in 104 cases of gonorrhea in women, twenty cases of gonococcal vulvovaginitis in inpatient children and twenty cases of gonococcal ophthalmia in inpatient infants. Of the 104 cases, forty were acute, twenty-seven subacute and thirty-seven chronic. Most of the patients were from 20 to 35 years of age. The method giving the best results was the administration of one tablet (0.5 Gm.) of sulfapyridine four times a day after food for one week. This was begun as soon as the diagnosis of gonorrhea was made. In addition, local treatment (the application of 10 per cent strong protein silver to the urethra and cervix) was carried out. This was given until the onset of the menstrual period following cessation of the drug, and thereafter once or twice weekly for another month. For the next four weeks the patients were examined once a week and local treatment was applied only if discharge or congestion persisted. Patients did not complain unduly of any ill effects. The criteria for cure required that all smears from the urethra and cervix for three months following the week of drug treatment should be negative. Nine women defaulted before observation had been completed, but of the remaining ninety-five 87.4 per cent, or eighty-three, fulfilling these requirements were cured. A study of these twelve unsatisfactory results showed that (1) inadequate dosage due to intolerance or faulty attendance for treatment was responsible for the failure to cure in four cases, (2) relapse occurred after local treatment had been missed for several weeks in one case, (3) there was no response to the drug in three cases and (4) after being negative during the administration of the drug and remaining satisfactory for varying lengths of time the gonococcus reappeared in spite of local treatment in four cases. Gonococcal complications cleared up without any treatment other than the administration of the drug. The dosage of sulfapyridine for the children with vulvovaginitis varied from a fourth of a tablet four times a day for one week in infants less than 3 months of age to half a tablet six times a day for one week in older girls. This was accompanied first by daily and then weekly vaginal swabbing with 10 per cent strong protein silver and the application of bismuth subgallate. The average duration of local treatment was four months, the limits being three and nine months. Only eleven cases were classified as satisfactorily cured. Further treatment of the cases not cured suggests the advisability of giving as a routine in all cases of gonococcal vulvovaginitis two courses of sulfapyridine separated by an interval of from ten to fourteen days. For the twenty cases of gonococcal ophthalmia the routine adopted was one-fourth tablet of sulfapyridine four times a day given with sodium bicarbonate, supplemented by irrigation with physiologic solution of sodium chloride, the frequency depending on the severity of the case. Smears from all the cases were negative within four days, even in two which had failed to respond to local treatment and protein shock. There were no relapses. The drug was discontinued forty-eight hours after the smears became negative. A total dosage of 3 Gm. sufficed in every case. The sulfapyridine was given crushed in milk to which a pinch of sodium bicarbonate was added. It caused no signs of intolerance.

Tuberculosis of Knee.—Murray reports the follow-up of 110 cases of tuberculosis traced from five to fifty-six years, average thirteen years, after the onset of the disease. In thirty-three cases of the synovial type there has been one death of pulmonary tuberculosis. In only one is the disease still active (five years after the onset), while in the others the disease is regarded as cured or quiescent. In ten there is a full range of movement and the joint is functionally normal, in eight limited painless movement varies from 20 to 100 degrees and in six

unsound ankylosis is present. Seven cases required arthrodesis; six resulted in bony ankylosis, the seventh in nonunion. Alteration in growth of limbs affected by synovial tuberculosis was observed in fifteen cases in the absence of focal bone changes; lengthening occurred twice as often as shortening. In seventy cases of the focal articular type there have been fifteen deaths. Eleven of these deaths were due to other tuberculous lesions, pulmonary and miliary tuberculosis and meningitis. In nearly all these cases, together with seven patients still alive in whom other tuberculous lesions developed, the primary tuberculous lesion was demonstrated in the knee. This type of tuberculosis of the knee, unfortunately the commonest, therefore must be regarded as a dangerous disease. Among the fifty-five living patients four have evidence of active disease in the knee joint, which in each case is unsoundly ankylosed, one of them following excision. The remaining fifty-one patients show no sign of active disease; thirty-two have sound ankylosis following excision, seven following conservative treatment, five have unsound ankylosis, three have a good range of movement in the joint and in four amputation was necessary. In five of the seven extra-articular cases the lesion healed without involving the knee joint, three having a full range of movement and two about half the normal range. In the remaining two cases the disease spread to the joint, one resulting in ankylosis and the other, following spread to the spine and kidney, ending in death. The majority of the synovial cases were treated conservatively on a Thomas splint, and excision was considered only when the lesion progressed to a focal articular type. Even in the focal articular group conservative treatment was carried out first in order to increase local and general resistance before excision or until the patient was considered old enough for excision. Following excision, bony union may occur after several years. Excluding one synovial case in which amputation was necessary owing to an accident, amputation was performed eight times because of the local condition. Four of these patients died, and four are alive and well, with the exception of the one who is now being treated for tuberculosis of the spine. In the extra-articular type two patients were subjected to evacuation of the abscess cavity, and both have a full range of movement. Three cases healed without operation and without involving the joint. Operation, therefore, does not appear necessary unless roentgenograms show the lesion to be spreading toward the joint. In the one focal articular case in which the lesion appeared to be confined to the patella, the patella was excised. This patient still has an unsound ankylosis after twelve years but there is no evidence of active disease.

Acute War Neuroses.—According to Sargent and Slater, cases of acute war neuroses, such as arose in the Flanders retreat, demonstrated that men of reasonably sound personality may break down if the strain is severe enough. This does not deny the importance of constitutional factors. Compared to an average population, this group of men would almost certainly show an excessive proportion who had suffered from nervous troubles in earlier life and an excessive frequency of psychiatric disorders in the blood relatives. Nevertheless these men had

shown a satisfactory adaptation to army life and the previous history showed in most cases a man of normal intelligence, personality and work record. The stress required to produce a breakdown of such personalities was of an altogether different order from any to which they could expect to be subjected in ordinary life. It was an accumulation of strains, both physical and mental, of great intensity. The clinical picture was surprisingly uniform. There were the signs of physical exhaustion: thin, fallen-in face, pallid or sallow complexions. The expression and the whole attitude of the body was one either of tension and anxiety or of a listless apathy. Neurologic signs of a functional nature were usually present. A coarse irregular tremor of the hands was common. The resemblance to a parkinsonian picture was often increased by an immobile facies, and the superficial resemblance was so great that a number of cases had been diagnosed as parkinsonism. Reflexes were usually exaggerated, occasionally sluggish. Mentally the patients complained of the usual symptoms of the acute anxiety state: sleeplessness, terrifying bad dreams, a feeling of inner unrest and a tendency to be startled at the least noise but particularly at the sound of an airplane going overhead or any sound resembling it. The course taken by these patients under treatment was uniformly toward improvement. The change in appearance in the first few days with adequate sleep and rest and food was striking. Tremors rapidly diminished in intensity, as did also the general attitude of tension. The degree to which recovery is complete is more doubtful. It seems that these patients have gone through a process for which the term conditioning may be used. The first essential of treatment is to secure rest. This may be done in the milder cases by confinement to bed for a few days and the administration of an effective hypnotic. This must be combined with a full diet and ample fluids. The best method of securing the essential sleep varies in different patients. For some a quickly acting drug with an effect that lasts only a few hours may be all that is necessary. But the majority find difficulty not so much in getting to sleep as in remaining asleep. For these a drug with a longer effective action will be required. A considerable number of the more severely affected will require a course of continuous narcosis. It will get them through the worst period of their convalescence without their being aware of the severity of their symptoms, and it helps to minimize the process of conditioning. Any of the standard methods of narcosis may be employed. The Mira method, employed in the Spanish civil war, has been found disappointing in some cases, since the narcosis was not always complete. As a rule, continuous narcosis has not been given for much longer than a week. It was found desirable to relieve acute hysterical symptoms, including amnesias, at the earliest moment by persuasion under hypnosis, produced directly or with the aid of intravenous barbiturate.

Treatment of Pneumonia.—McSweeney compares the results of different methods of treatment in 478 unselected consecutive cases of lobar pneumonia treated in Cork Street Hospital. In the years from 1931 to 1933 a consecutive series of 120 cases were treated with daily intravenous injections of an 0.8 per cent suspension of a preparation containing iodine in combination with the colloidal and semicolloidal decomposition products of proteins (collosol iodine) until the crisis was reached. Of these, sixteen (13.3 per cent) died. In 172 cases antipneumococcus serum was used alone or in combination with the colloidal iodine. Death occurred in twenty-five (14.5 per cent) of these. In the 186 cases in which antipneumococcus serum was given together with sulfanilamide or, more often, with sulfapyridine, the mortality was 2.7 per cent. At present, antipneumococcus serum and sulfapyridine are used in lobar pneumonia at the author's hospital. The author presents results obtained with different methods of treatment in 171 unselected consecutive cases of bronchopneumonia admitted to the same hospital. With antipneumococcus serum alone the case mortality was 43.7; with antipneumococcus serum and sulfonamide (mostly sulfanilamide) 38 per cent in 1937 and 34 per cent in 1938, and with antipneumococcus serum and sulfapyridine 9.5 per cent. The great majority of the patients treated were children under 5, and the case mortality in this group was reduced from 50 per cent in 1936 and 1937 to 30 per cent in 1938 and to 10 per cent in 1939, the first complete "sulfapyridine" year.

Lymph Stream in the Blood, Interstitial Clefts and Lymph Tracks. O. Müller.—p. 617.

*Oral Chemotherapy of Gonorrhea. G. Miescher.—p. 621.

Electrocardiographic Observations in Dissecting Aneurysm of Ascending Aorta. F. Wuhmann.—p. 627.

Oral Chemotherapy of Gonorrhea.—Miescher reports on oral chemotherapy of 964 cases of gonorrhea. Of the substances used sulfathiazole and sulfapyridine gave the best results. The drugs were administered in decreasing doses within a period of six days, 18 Gm. in all. They appeared to be equally effective in new and old, simple and complicated cases. Vaccinotherapy and local treatment were also employed. The significance of the latter appeared to be small. The percentage of cures after a single treatment was 97 and 95 respectively, with men responding somewhat better to sulfathiazole and sulfapyridine. With the time required for observation and control by provocation, men were cured in from fourteen to sixteen and women in from twenty-five to forty days. The author points out the danger of intoxication and intolerance in the oral chemotherapy of gonorrhea. Of the drugs used sulfathiazole was tolerated best. It appeared to be the most effective and best tolerated antigonorrheal preparation.

Hydrolyability in Infants. M. Laguarda.—p. 433.

*Treatment of Acute Purulent Pleurisy in Children. R. B. Yannicelli.—p. 460.

Treatment of Acute Purulent Pleurisy in Children.—Yannicelli reports satisfactory results from closed thoracic drainage in a group of twenty infants and children with acute purulent pleurisy. The majority of the patients were between the ages of 3 months and 5 years. The treatment consists of draining the pleural cavity through a number 16 Nelaton catheter which is introduced through the orifice of a trocar puncture. Drainage is practiced by repeated aspiration of pus with a syringe and the catheter is left in place, closed with a clamp and fastened to the chest wall for further aspirations. At the first aspiration only from 100 to 400 cc. should be removed. Further aspirations are made at convenient intervals and in amounts of not more than 20 cc. at each aspiration in order to prevent sudden intrapleural changes. When slow decompression is indicated and when the amount of fluid is scanty, the drainage is changed into a permanent one by attaching the distal portion of the catheter to a siphon tube, the distal portion of which is placed in a receptacle containing aqueous solution of sodium hypochlorite. The catheter is frequently clamped for a few minutes for temporary discontinuation of drainage. Lavages through the sound with aqueous solution of sodium hypochlorite are indicated when the pus is thick or fetid, in the presence of false membranes and in gangrenous pleurisy, except when a bronchopleural fistula is suspected. The treatment as a rule is effective in controlling acute purulent pleurisy in from two to five weeks. The catheter is removed one or two days after complete evacuation of pus. Before the drain is removed the condition is ascertained by x-ray examination. There were fifteen recoveries in the group of twenty cases reported by the author. Some of the deaths were caused by general sepsis rather than by the pleurisy. The author concludes that the treatment is simple, is well tolerated and causes neither shock nor sudden intrapleural decompression. Rib resection becomes unnecessary. In the few cases in which there exist indications for ample drainage, the closed thoracic drainage can be converted into a wide one.

*Clinical Diagnosis of Segmental Trunk Occlusion in Arteritis of Lower Limbs. E. C. Palma.—p. 340.

Clinical Diagnosis of Segmental Occlusion in Arteritis.—Palma found that segmental trunk occlusion of the lower limbs is a frequent complication in juvenile or senile arteritis. Arteriography is a reliable diagnostic method not

commonly resorted to because it lacks simplicity. In the presence of typical arterial intermittent claudication, clinical diagnosis can be made from the following symptoms: (1) early disappearance of pulsation of the posterior tibial, dorsalis pedis and popliteal arteries in the presence of normal pulsation in the same arteries in the opposite limb, (2) diminution or disappearance of oscillometric oscillations in the middle or lower portion of the thigh of the involved limb in the presence of normal oscillations at the same points in the opposite limb and (3) pain or cramp in the calf of the involved limb on walking. Claudication may be of short or long duration, provided the disturbances of the peripheral circulation are slight. Pulsation of the femoral artery is determined by palpation in Scarpa's triangle. Popliteal pulsation is determined with the patient's limb in Buerger's position. These results may be further investigated by vasodilating tests such as the warm bath of Babinski and Heitz, induced hyperthermia and spinal and sympathetic lumbar anesthesia. The upper limit of occlusion is ascertained by the point of disappearance of arterial oscillations. The extent of the lesion is surmised from the acuteness of peripheral functional disorders, which are acute when the occlusion is low and several arteries are involved, and moderate when the occlusion is high and only one artery is involved. The author believes that clinical diagnosis based on the symptoms is important and may be relied on in many instances as an indication for operative intervention without recourse to arteriography.

*Thymus Rests in Exophthalmic Goiter. R. Finochietto and S. E. Luchetti.—p. 461.

Humoral Syndrome Complicating Surgery of Bile Ducts. R. S. Ferracani.—p. 504.

Thymus Rests in Exophthalmic Goiter.—Finochietto and Luchetti found, in the course of thyroidectomies, rests of the thymus microscopically verified in eight cases of exophthalmic goiter. The rests consisted of a cord of fibrous connective tissue or a lamina of fibrous and fatty tissue. The cord with or without nodules of thymic tissue was in continuity with one of the lower poles of the goiter and extended to the mediastinum behind the sternum. The lamina had their origin at the thyroid isthmus, covered the trachea and extended into the mediastinum. The authors found that these formations were not connected with real aberrant thymic gland but that they may be connected with intrathoracic goiter. These structures must be removed in the course of a thyroidectomy because they interfere with the removal of the lower pole of the goiter. Their course should be followed up to the point at which they disappear into the mediastinal tissues, in order to disclose the presence of an intrathoracic goiter, the persistence of which after an operation might give an erroneous interpretation of the results of the operation.

Bibliotek for Læger, Copenhagen**132:121-135 (April) 1940**

*Considerations on Prognosis in Suppurative Coloproctitis. O. Moltke.—p. 121.

Prognosis in Suppurative Coloproctitis.—Moltke found hemoglobin values under 60 per cent in one fifth of the patients with suppurative coloproctitis who recovered and over 80 per cent in one third of the fatal cases and therefore considers the anemia in this disorder of doubtful significance as a prognostic sign. The relation between the cells with segmented nuclei and the immature neutrophil cells in the blood, however, seems to him an exceedingly important expression of the gravity of a case. He says that all the cases in his material with a shifting to the left of over 30 per cent were fatal, while only one patient with a shifting to the left of less than 30 per cent succumbed. Less marked shifting was seen in the moderately grave cases in which remission was possible, and normal values only in the mild cases. A low sedimentation rate may also be regarded as a favorable sign.

THE TREATMENT OF ARTERIO- SCLEROSIS OBLITERANS

SOCIAL SIGNIFICANCE AND ULTIMATE OBJECTIVE

CHAIRMAN'S ADDRESS

IRVING S. WRIGHT, M.D.

NEW YORK

The problems presented by the development of arteriosclerosis are of overwhelming magnitude both medically and socially. Their potential significance is, nevertheless, for the most part hopelessly underestimated. Yet, unless satisfactory solutions are found for the varied facets of this massive loadstone, it may prove too heavy for our present civilization.

Once before when our civilization was threatened by the weight of a great problem, a then little known man, Abraham Lincoln, suggested a mental approach which appears equally applicable to the present: "If we could first know where we are and whither we are tending, we could better judge what to do and how to do it."

For centuries men have sought the secret of longevity. The alchemists, soothsayers and astrologers flourished in the courts of many dynasties that they might prolong the lives of the rulers. The search for this secret drove men such as Ponce de Leon to the ends of the earth, to no avail.

The average span of life still remained under 40 years, although a certain percentage of the population did manage to achieve longevity. During the nineteenth century, however, in many laboratories, scientists were quietly bringing to light facts which within three short generations have markedly changed this situation. Pasteur, Koch, Semmelweis—their names are almost legion—made possible the tremendous saving of infant life; the practical elimination of many of the worst scourges from the modern nations, such as yellow fever, cholera and bubonic plague; the marked reduction in death from infectious and contagious diseases, such as pneumonia, tuberculosis and diphtheria, and a much better understanding of proper hygiene and nutrition. It has been with just pride that the medical and public health workers have pointed to the reduced mortality and morbidity rates of the population and to the fact that no group of people of equivalent size has ever achieved the health record enjoyed by the citizens of the United States. Except for a few students of trends, however, the ultimate effects of this change have not been foreseen too clearly or with sufficient analytic acumen. True, it is recognized that in 1850 the average length of life was 42 years, whereas it is now more than 60 years. In

this country there has been an increase of nearly 20 million persons in the age groups over 50 years. All of these are potential victims of arteriosclerosis unless some other disease factor produces death first. Over the age of 65 the senescent vascular changes become increasingly frequent and serious whether they affect the brain, heart, kidneys, extremities or some less vital tissues. Incapacity is usually prolonged, often lasting years, yet demanding the most exacting medical care. It is estimated that in 1980 the number of persons over 65 will be double that of today. Such predictions are not, however, always accurate. *Blackwood's Magazine* predicted in 1860 that the population of the United States in 1940 would be 303,000,000.

It is obvious that, now that the long sought for lengthening of life is available for a much larger portion of the population, it comes as a mixed blessing for which careful planning is required.

Neither the economic nor the medical aspects of this situation appear susceptible of solution in the light of our present knowledge. Prolonged and detailed experimental studies and careful critical analyses will be necessary before an intelligent approach can be attempted.

While the facets include economic, sociologic, psychiatric and other phases, this presentation must of necessity deal more directly with the medical aspects of the situation. I will therefore examine some of the facts in this regard. While the earliest evidences of arteriosclerosis are known to occur under the age of 40 there are definite degenerative changes present somewhere in the arterial trees of practically all individuals over the age of 50. All blood vessels regardless of what tissues or organs they may supply should be considered a part of the peripheral circulatory system. This conception is vital for the understanding of the problem, clearly pointing out the serious prognostic significance of one arteriosclerotic crisis for any or all other arteries and arterioles in the body of the individual. Since each decade is producing approximately half a million additional candidates for these complications, the potential problem is increasing at a serious rate.

CORRECT DIAGNOSIS

An important step toward clarifying the picture, therefore, could be achieved by a reclassification of this pathologic condition in mortality and morbidity tables. Thus, for accuracy, conditions should, when correct, be diagnosed:

Arteriosclerosis with secondary diabetes mellitus instead of diabetes mellitus with arteriosclerosis.

Arteriosclerosis of the cerebral vessels with thrombosis or hemorrhage rather than apoplexy.

Arteriosclerosis of the renal vessels rather than Bright's disease or chronic nephritis, or arteriosclerosis of the vessels of the legs instead of senile or diabetic gangrene.

If this principle were applied to the classification of the process in all organs including the coronary arteries

of the heart, the statistics would then be properly weighted and the tremendous significance of this trend would at once be obvious to all. It would be more widely recognized that of the proportion of the population over 50 years of age 60 per cent (15 million) will die of some cardiovascular-renal syndrome whereas only 9 per cent will die of cancer. A very large but as yet undetermined portion of that 60 per cent will die as a result of degenerative changes of the arteries with the cardiac, renal or other syndromes merely the results of secondary ischemia or hemorrhage.

As these syndromes frequently produce prolonged and painful disability before death, a change in philosophical approach might well be considered. Perhaps the mere prolongation of life should no longer be sought as the highest goal but rather longevity only to such a degree as it is compatible with happiness and a full life free from pain and invalidism.

It is necessary to understand the mechanisms involved before we can hope to solve the enigma of arteriosclerosis. The gaps in our knowledge are formidable. We do not know for a certainty whether this condition should be correctly classified as a disease or a degenerative process, although more recently the trend has been toward the latter designation. It is not impossible, however, that further investigation may reverse this trend.

We do not know what causes this process to take place. The etiologic factors which have been the subject of study are many, including age, diet, physical work, worry, climate and infections, yet definite proof is lacking which would make it possible to state that arteriosclerosis is a direct result of any one of these factors.

We do not completely understand the biologic phenomena by which these changes take place. Whereas arteriosclerosis can be readily produced by the feeding of cholesterol to rabbits and this can be prevented by iodides, thyroid extract, pancreatic tissue extracts and other substances, the difference in the metabolism of the herbivorous rabbit and man as regards cholesterol does not justify direct inferential conclusions.

Winternitz and his co-workers have shed interesting light on the possibility of the development of arteriosclerotic plaques from hemorrhages of the vasa vasorum. The importance of this factor has been disputed by others. Certain authors have advocated theories of direct stress and strain, dehydration, heredity, endocrine changes, vitamin deficiencies and other possibilities. Perhaps each of these factors has certain importance but we are still at a loss as to why one man develops generalized arteriosclerosis at 35 years of age with no apparent cause, whereas another man escapes equivalent involvement until he is 65. It seems likely that the incidence of sclerosis in general increases with age because of the accumulation of traumas, namely the aforementioned etiologic possibilities, during the passage of years. These factors may not, however, operate in the instance of a specific individual.

THERAPY

In spite of this situation, important contributions have been made toward the physiology and pharmacology of the normal and impaired circulation. The scope of this presentation does not permit a review of the voluminous literature on this subject. A valuable symposium appeared in the February issue of the *Archives of Surgery*. Certain principles of therapy have been evolved as a result of the combined efforts of

many workers which have favorably influenced the outlook of the individual with arteriosclerosis obliterans. It is difficult to determine at this time whether the average longevity is actually increased by these methods. Whereas in one individual the control of infection with healing of a gangrenous foot may definitely prolong his life, another patient may die earlier because his intermittent claudication distance was markedly prolonged by treatment, thus producing an increasing strain on a damaged heart with a resulting failure. I have seen what appeared to be striking examples of each of these groups. One common objective was achieved in each group, a more satisfactory life. In the first instance the gangrene was healed and the patient restored to a life of activity and freedom from pain. The second patient, who had been enabled to walk but half a block and hence could scarcely be classified as more than a semi-invalid, became able to walk from six to eight blocks, returned to business and regained his interest in life and finally increased his walking to a greater extent. After playing nine holes of golf he suddenly developed an acute decompensation, probably associated with a coronary occlusion, and died. It is not certain but seems probable that his life of semi-invalidism might have been of longer duration. The choice of the majority of the patients with whom I have frankly discussed this elective has unhesitatingly been for the fuller if shorter life.

The trend in recent years has been toward conservative therapy as against radical surgery. Marked success has resulted from this trend in the treatment of the organic occlusive disease thrombo-angiitis obliterans. The major amputation rate, which formerly averaged about 70 per cent, is now averaging from 3 to 10 per cent in several leading vascular clinics. Arteriosclerosis obliterans has been less responsive to conservative therapy for numerous reasons, a few of which follow:

1. We are dealing with older tissues with less resistance to infection and less capacity for regrowth.
2. A large percentage of these patients are seriously handicapped by diabetes mellitus, arteriosclerotic renal disease, heart disease or other complications.
3. The point of blockage in arteriosclerosis obliterans is frequently, though not always, quite far proximal, thus blocking a large arterial trunk and reducing the possibilities for collateral circulation, whereas characteristically thrombo-angiitis obliterans begins by involving the minute distal vessels, very slowly extending proximally, giving the collateral vessels a better opportunity to establish their functional capacity to the ischemic tissues in response to metabolic demands.
4. Spasm plays a less important part in arteriosclerosis obliterans than in thrombo-angiitis obliterans, and hence therapy directed at the production of vasodilatation is, as would be expected, less effectual.

In spite of these handicaps, definite improvement in the amputation rate has been achieved by the selective and considered use of the following important technics and medications:

1. Rest of the involved extremities in a controlled temperature of from 88 to 94 F.
2. Soaks and baths at similar temperatures, using only mild solutions such as saline, boric acid or azochloramide in triacetin 1:500.
3. Heat applied to the abdomen, producing reflex vasodilatation.
4. Postural exercises, preferably passive, by means of the oscillating bed described by Sanders.
5. Pressure-suction boots in a few selected cases.
6. Alcohol in the form of spirituous liquors by mouth.

7. Deproteinized and other pancreatic tissue extracts by intramuscular injections.
8. Extreme general care in the protection of the feet.
9. Meticulous attention to any open lesions, using only correct technic in their care.
10. Control of diabetes or other complications.
11. The judicious use of the sulfanilamide compounds in the presence of infections, selection being based on the organism present, if possible.

Of almost equal importance is the necessity of avoiding:

1. The use of tobacco.
2. The use of heat greater than 96 F., applied to the extremities—especially in the form of hot water bottles, heat pads, infra-red, diathermy and short wave machines.
3. The use of strong antiseptics.
4. Meddlesome surgery in unskilled hands.

Of probable or possible value in the treatment of other vascular diseases, but of questionable value in the treatment of arteriosclerosis obliterans, in my experience are:

1. Typhoid vaccine.
2. Saline or other solutions intravenously.
3. Intermittent venous hyperemia.
4. Mecholyt iontophoresis.
5. Sympathetic surgery.
6. Vasodilating drugs, nitrites and theobromine compounds.
7. Papaverine, except for its opiate effect.

Certain points should be carefully considered before amputation of an extremity is decided on:

1. The extent and spread of infection of the local lesion. Rapidly spreading highly infected gangrenous areas sometimes demand amputation to prevent septic death. These are now subject to better control with the use of the sulfanilamide group.
2. The level of blockage of the major arterial trunk of the affected extremity, the amount of compensatory reserve and the collateral vessels active. These facts can be ascertained by the use of the oscillogram, thermocouple readings with vasodilator tests, arteriographic studies, ergometric tests, histamine flare tests and other methods. Amputation should be high enough to avoid the need for secondary surgery.
3. The status of the remainder of the peripheral circulation. This is particularly important when one leg is involved. Examination frequently reveals that the circulation is actually poorer in the opposite leg, but, having escaped trauma, no open lesion has as yet appeared. Amputation of one leg in these cases is not infrequently followed shortly by the need for repetition in the second leg. It is therefore of vital importance to be conservative if possible in such a case.
4. The age and general condition of the patient. It should be remembered that about 50 per cent of arteriosclerotic patients fail to learn to walk on an artificial limb after a midhigh amputation and that such a patient cannot usually be said to be living a full or useful life. Diabetes, when present, seriously complicates the entire picture, whether one wishes to be conservative or radical.

While it is easier to study the circulation of the extremities, information thus obtained may help to understand similar processes occurring in less accessible blood vessels.

A PROBLEM OF UNRECOGNIZED SIGNIFICANCE

The vastest of all medical problems of the future, arteriosclerosis, it remains the most neglected. The medical schools for the most part give woefully inadequate training in its study and care. Too frequently the practicing physician fails to recognize its manifestations until gangrene has occurred. The public cares little for what it considers the vagaries of old age, although all who achieve old age are liable to them. The foundations have failed to recognize its importance

and have with few exceptions, notably the Josiah Macy Jr. Foundation, concentrated on more spectacular diseases of lesser fundamental importance to our civilization. Too few research workers have engaged in its study, to a large extent because of lack of endowment. Truly, it has been a neglected field in proportion to its importance.

Here is a great opportunity for young men entering into the field of medicine for clinical and animal research. This presentation may be regarded as a challenge to them to determine the ultimate objectives in the field of geriatrics.

Man has the unhappy faculty of producing mechanical and biologic frankensteins without developing properly balanced factors with which to exercise suitable control. Witness the present world conflicts, technologic unemployment and this problem of how to handle the aged. The question may well be raised as to whether we should justifiably bend our efforts toward the further prolongation of life unless we are prepared to insure that increasing age will bring happiness to the individual and avoid unbearable hardship on the community.

400 Madison Avenue.

STUDIES ON PRESERVED HUMAN BLOOD

VI. REACTIONS FROM TRANSFUSION

ELMER L. DeGOWIN, M.D.

AND

ROBERT C. HARDIN, M.D.

IOWA CITY

When considering the use of preserved blood, the clinician is confronted with two fundamental questions: 1. Is the administration of preserved blood efficacious? 2. Is the transfusion of stored blood safe? This report is an attempt to answer the latter question by a study of the incidence of reactions occurring in 2,423 blood transfusions.

The first transfusions of preserved blood were administered by Robertson,¹ working in the casualty clearing stations of the British army in 1917-1918. Utilizing the blood-dextrose-citrate mixture developed by Rous and Turner,² he gave twenty-two transfusions. A slight chill in one recipient was the only complication. With the recent development of blood banks in the United States has come the opportunity of studying the incidence of reactions in large series of transfusions. Belk, Henry and Rosenstein³ reported jaundice or hemoglobinuria as a complication in seven of 400 transfusions. The incidence of chills, fever and urticaria was 10 per cent. In a series of 220 transfusions, Vary and Krah⁴ had an incidence of definite reactions of all types of 7 per cent and total possible reactions of 13

From the Department of Internal Medicine, State University of Iowa College of Medicine.

Read before the Section on Pathology and Physiology at the Ninety-First Annual Session of the American Medical Association, New York, June 14, 1940.

per cent. In 1,415 transfusions, Diggs and Keith⁵ reported reactions occurring in 6.7 per cent of the series.

The bases of the present report are the observations on a series of 2,423 blood transfusions, in 295 of which fresh blood was employed. The remaining 2,128 utilized blood stored from one to thirty-eight days at 3-5 C. Two types of preservative were used. The blood-citrate mixture comprised 500 cc. of blood plus from 50 to 100 cc. of 3.2 per cent sodium citrate in distilled water. This blood was regularly discarded after ten days of storage because of extensive hemolysis. The blood-dextrose-citrate mixture consisted of 500 cc. of blood, 650 cc. of 5.4 per cent dextrose in

refrigerated blood before administration. We have shown previously⁷ that this is a safe procedure.

Whenever practical, the urine of the patient was made alkaline before transfusion by the oral administration of sodium bicarbonate in the hope of preventing anuria, should hemoglobinuria occur.⁸ With the exception of a few instances, the group of the transfused blood was the same as that of the recipient. Within twenty-four hours after the transfusion a member of the team visited the recipient, inspected the clinical record and personally analyzed for hemoglobin the urine passed since transfusion. Tests for blood compatibility were repeated in many instances when chills and fever occurred.

TABLE 1.—Incidence of Reactions from Transfusions of Preserved Blood

water and 100 cc. of 3.2 per cent sodium citrate in water. This is a modification of the Rous-Turner solution and has been described elsewhere.⁶ Blood preserved in this solution was used for transfusions when over thirty days old. All the blood was collected by members of a team working in the Blood Transfusion Laboratory of the University Hospitals. Most of the donors were relatives or friends of patients. They were of both sexes and between the ages of 18 and 60 years. The blood typing and cross-matching were performed exclusively by technicians in the laboratory. The transfusions were administered by the interns attending the recipients. The blood mixture was allowed to flow into the vein by gravity through a 20 gage needle. No attempt was made to warm the

The most frequent type of transfusion reaction proved to be the occurrence of chills and fever appearing during, or a few minutes after, the administration of the blood. This phenomenon occurred in 2 per cent of all transfusions. The temperature was usually down to normal within eight hours. In 0.9 per cent of the transfusions the recipients were observed to have chills or chilly sensations during or immediately after the administration of the blood, yet the body temperature remained normal. It was not thought that this reaction could be due to the temperature of the transfusion mixture since the incidence was so small. It was assumed rather, though not proved, that it was the result of the injection of small doses of pyogens.

Urticaria or angioneurotic edema occurred in 1.1 per cent of all transfusions. In some cases the symptoms were so severe that the transfusion was discontinued. It was observed that some patients receiving multiple transfusions were more susceptible to this manifestation than others. No correlation could be found between the occurrence of urticaria and a history of allergic symptoms in either donor or recipient. It seems unlikely that the high plasma potassium content of the preserved blood was responsible, since there was no increase in incidence with transfusion of bloods of greater age.

In a previous paper⁶ it has been shown that hemolysis is detectable in blood stored less than five days and that the rate of hemolysis varies greatly, depending on the preservative used. One criterion for the suitability of preserved blood for transfusion, therefore, is the amount of extracellular hemoglobin in the plasma. When the limits of storage are sufficiently rigid, hemoglobinuria should not occur from this factor. In five recipients of the series hemoglobinuria occurred. None of the patients suffered ill effects. In two the condition was deliberately produced by the injection of 11.8 Gm. and 1.6 Gm. of extracellular hemoglobin respectively. Another patient receiving 1.8 Gm., however, did not excrete any in the urine. Two other recipients belonging to groups A and AB, respectively, received preserved blood of group O containing little plasma hemoglobin (1 mg. and 721 mg. respectively), but they excreted hemoglobin in the urine. It is possible that the agglutinin and hemolysin titers of the donor's serum were so high that dilution by the recipient's blood did not inactivate it.

Some writers have reported a rather high incidence of jaundice from the transfusion of preserved blood. It occurred only once in our series. A woman received a transfusion without symptoms or signs of untoward reaction. The next day she was observed to be jaundiced. The serum van den Bergh reaction was 5.5 mg. per hundred cubic centimeters (indirect). The icterus disappeared in a few days; no hemoglobinuria occurred nor could free hemoglobin be detected in the blood serum eighteen hours after the transfusion. The fact that she had been receiving sulfanilamide for the preceding week may have been a contributing factor.

Two deaths occurred from blood transfusions. A woman belonging to group O received group A blood through a series of errors in the laboratory. When about 100 cc. of the blood had been given, the transfusion was discontinued because of the appearance of marked dyspnea, cyanosis and a feeling of constriction in the chest. The patient rapidly developed signs of shock and, in spite of the administration of epinephrine and transfusion with compatible blood, she died within six hours. A high content of extracellular hemoglobin was present in the blood serum of the recipient. The time of survival was not sufficient to determine whether renal insufficiency had developed. An infant weighing 7½ pounds (3,400 Gm.) was given 800 cc. of blood-dextrose-citrate mixture in the jugular vein. Cyanosis, dyspnea and generalized edema developed suddenly. Death occurred thirty-six hours later from circulatory embarrassment. Neither of these reactions was chargeable to the use of preserved blood per se.

When the reactions of all types are tabulated in categories corresponding to the age of storage of the blood (table 1) it will be noted that there is no significant

correlation between the incidence of reactions and the age of the blood used. Nor is there a significant difference in reactions from the two types of preservatives employed. This statement should be qualified by stating that the limit of storage for the blood-citrate mixture was ten days while for the dextrose-citrate preservative the age limit was thirty days. No types of reactions were encountered from the use of preserved blood which were not already known to be complications of transfusions with fresh blood.

The manufacture of dextrose, saline and sodium citrate solutions, as well as the preparation of all apparatus used for intravenous administration of fluids and blood, was performed under unified supervision. Data were thus available which shed some light on the part played by pyrogens⁹ in producing febrile transfusion reactions. Over a ten month period the incidence of chills only or of chills and fever from intravenous

infusions was compared with the incidence of the same type of reactions occurring in blood transfusions (table 2). It was found that when the pyrogenic reactions from fluids were frequent there was a corresponding increase in the same type of reactions from blood transfusions. However, the incidence was always much higher in blood transfusions than in intravenous infusions. The only factors concerned in transfusions which were not present in the infusion were sodium citrate and blood. It is possible that pyrogens were present in the citrate solutions or that organisms were introduced during the collection of blood.

CONCLUSION

1. The incidence of all types of reactions was no greater from the transfusion of preserved blood than when fresh blood was used, provided proper care was taken in storing and handling it. The limits of storage time were arbitrarily placed at ten days for citrated blood and thirty days for the dextrose-citrate mixture.
2. Variations in the age of the blood used caused no corresponding variation in the incidence of reactions.
3. No types of reactions occurred from preserved blood which are not recognized as complications from transfusions of fresh blood.

4. The presence of pyrogens in fluids or apparatus is probably a cause of many febrile reactions during the transfusion of blood.

ABSTRACT OF DISCUSSION

DR. ALEXANDER S. WIENER, Brooklyn: The experiences of the authors with 1,940 transfusions of bank blood within a year place them in a position to evaluate the merits and demerits of preserved blood. They have an enviable record, considering the low incidence of transfusion reactions encountered, which is practically the same as our own reaction rate, though at our institution only fresh blood is used for transfusions. My experience with transfusions of bank blood has been limited to about thirty cases, rather intensively studied from the standpoint of the fate of the transfused erythrocytes in the patient's circulation. For this study, which was carried out in collaboration with Dr. George Schaefer, we made use of antisera for the agglutinogens M and N of human red cells. Since these agglutinogens play no part in transfusion reactions they are disregarded when selecting donors for transfusion. For example, a patient of group A, type M, may be given blood of type AM, AN or AMN. When the M, N types of donor and patient differ the fate of the donor's cells in the patient's circulation can readily be traced with the aid of anti-M and anti-N agglutinating serums. Using this technic we found that, while fresh blood survived for periods up to 120 days in the patient's circulation, the maximum length of life of the transfused cells diminished roughly in proportion to the period of storage *in vitro*. In two cases in which transfusions of blood 20 and 21 days old respectively were given, the cells completely disappeared from the circulation of the patients within twenty-four hours. Based on these results we advised that the maximum period of storage of blood for transfusion be set at from seven to ten days. In our studies the blood taken for transfusions was kept in citrate solution; it is possible that the period of usefulness of the bank blood may be extended by the addition of dextrose as advocated by Drs. DeGowin and Hardin. However, from experiences on the preservation of blood cells for blood grouping my impression is that the fragility of the cells increases almost as rapidly when dextrose is added, even though the cells appear intact to the naked eye for longer periods. With regard to the occurrence of jaundice after transfusions of bank blood, we had only one experience, a gravely ill patient who had been given blood nineteen days old. The patient was reported to have become jaundiced during the two hours consumed by the injection of the blood, and the jaundice progressively deepened until the time of his death, six hours later. Many more cases of latent icterus were picked up by examining the patient's blood a few hours after the transfusion. The serum separated from this blood sample was noticeably icteric in comparison with the pretransfusion blood serum almost regularly in patients receiving blood more than one week old, while icterus did not occur when fresher blood was used.

DR. L. W. DIGGS, Memphis, Tenn.: The blood bank of the John Gaston Hospital, which is the charity hospital of the city of Memphis, has been in continuous operation since it was started in April 1938. The use of preserved blood has been accepted by the clinical staff as a practical and relatively safe procedure superior to the old volunteer system and particularly advantageous in the surgical and maternity services. During the first year of operation of the bank, 1,415 transfusions were given with a reaction percentage of 6.7 and five transfusion deaths, one of which was due to mismatching. During the second year 2,140 transfusions were given with 8.1 per cent reactions and one transfusion death. The reaction percentages for single months varied from 2.2 to 14.1. To test the effect of giving cold blood and to compare reactions with blood artificially warmed, an experiment was started in which the bloods were on alternate weeks warmed and on the next week given without warming except to the degree to which the equipment and tubing were exposed to room temperature. In 869 consecutive transfusions the reactions varied widely in various weeks, but there was no apparent relation between the reaction percentage and the temperature of the blood. The febrile reactions following the giving of 427 transfusions of cold blood

were 8.2 per cent and the reactions following the giving of 442 transfusions of warm blood 7.9 per cent. The warming of blood takes time and requires special equipment. Warmth favors bacterial growth and cell disintegration. Overheating of blood is extremely dangerous and readily occurs when the heating is entrusted to inexperienced student nurses. One of our transfusion deaths was attributed to overheating of the blood. In the early days of the bank, when the bloods were heated in the wards, occasional flasks of blood were cooked on gas ranges. We think that it is safer to give blood cold than to attempt to warm it. The giving of hemolyzed blood is likely to result in reaction. A simple test of hemolysis which we regularly use is to collect a test tube of blood from the transfusion set at the time the blood is filtered in the giving flask. This blood is centrifuged and the supernatant fluid examined. When the concentration of hemoglobin in the supernatant is 100 mg. per hundred cubic centimeters or above, the fluid is definitely discolored and is considered to be unsafe for use. The rate of hemolysis of blood preserved by refrigeration in citrate solutions varies widely in different bloods, but the average rate of increase in hemoglobin in the supernatant plasma is about 10 mg. daily per hundred cubic centimeters and by the tenth day there is often gross hemolysis, and by the fourteenth day gross hemolysis is the rule.

DR. HYMAN I. GOLDSTEIN, Camden, N. J.: Because of a tragedy in my family last fall as the result of a blood dyscrasia I rise to ask a question. Our efforts have always been in the direction of the erythrocytes—compatibility tests and cross matching have been limited to the red blood cells. Why not increasing interest in the direction of the leukocytes, thrombocytes and kinetocytes, and the possibility of certain reactions after transfusions being due to these other cellular elements? It appeared to me in the case cited that the blood transfusions did not help and perhaps purged the few (normal?) white blood cells that the patient had as a result of acute myeloblastic leukemia, probably because of some unrecognized reactions. In reference to the cold blood used by the authors, I cite an experience in the case of a Newark physician who developed auto-agglutination with severe hemolytic changes, owing in part at least to the changed temperature of the blood. Luck and good fortune must have played a part in the authors' studies. Much progress has been made since Hieronymus Cardanus (1501-1576) and Magnus Pegelius (1593) mentioned the possibilities of transferring blood directly from the vessels of one person to those of another. Uncountable contributions to our knowledge of the blood and the use of blood transfusions have been contributed to the literature since Andreas Libavius (1615) first advocated blood transfusion and Johannes Colle of Padua suggested such a procedure. One need only mention the earliest contributions by Christopher Wren (1656), Richard Lower (1665), Jean Baptiste Denis, and Lower and King (Nov. 23, 1667). I wish to compliment Drs. DeGowin and Hardin on their studies on preserved human blood.

DR. ALVIN G. FOORD, Pasadena, Calif.: Most of the discussion concerning the use of preserved blood for transfusions has been limited to the changes in the red cells, and the previous discussor from Camden has brought up the question of the leukocytes. It appears to me that more should be said concerning the plasma, particularly changes in complement or opsonin content resulting from preservation. Little information is available except the work of Kolmer, who found rather rapid decrease in complement in a few days of refrigeration. Since about half of the transfusions in an average hospital are given in cases of severe infections with the idea of boosting the patient's resistance, partially at least from the effect of addition of opsonins, more information on the plasma should be obtained. I should like to hear from the speaker on this phase of the transfusion problem.

DR. ELMER L. DEGOWIN, Iowa City: It was my purpose to limit the discussion to the safety with which preserved blood can be given. The question of the efficacy of stored blood obviously cannot be settled in the time allowed nor is there enough information available at present to arrive at a satisfactory conclusion. Definite objective evidence of therapeutic effect can seldom be obtained from patients receiving transfusions because the picture is complicated by the course of the

primary disease and by other therapeutic measures. It is much less difficult to determine whether a transfusion is harmful. Aplastic anemia is one of the few clinical conditions in which one can decide whether transfused erythrocytes are fulfilling their physiologic function. We have under our care a patient with aplastic anemia who has been kept alive for the last eighteen months with transfusions of preserved blood. He receives a liter of stored blood every three weeks and is thus enabled to carry on his work. If the interval between transfusions is extended to four weeks, he returns with a lower erythrocyte level than after the three week interval. Because of our observations on this patient I am at a loss to interpret Dr. Wiener's experience in which the transfused agglutinogens disappeared so rapidly from the blood stream. The objection was raised that red cells stored with dextrose showed markedly increased "fragility" in hypotonic saline solutions. This is true but it has no clinical significance. Red cells are permeable to dextrose and therefore swell. The fragility test is merely an indirect measure of cell size. Erythrocytes swelling in dextrose solutions can be reduced again to normal size by washing with isotonic saline solution. Dr. Wiener referred to the increased color of the recipient's serum a few hours after transfusion as indicating hemolysis. It is important to determine whether the pigment resulted from cells which hemolyzed in the body or from the free hemoglobin which is practically always present in the plasma of stored blood. The question has been asked whether the leukocytes can be supplemented by transfusion of preserved blood. We cannot demonstrate any increase in the recipient's leukocytes after the transfusion of either fresh or preserved blood. By the term "cold blood" we refer to the preserved blood mixture which has not been deliberately heated. Actually, if blood directly out of the refrigerator is placed in the usual gravity apparatus for administration it soon approaches the temperature of the room as it passes through the rubber tubing. Dr. Kolmer has studied the rate of disintegration of complement during storage. I believe he found that the titer became low after ten days in the refrigerator.

POSTOPERATIVE ATELECTASIS

THE ANESTHETIST'S PART IN THE DIAGNOSIS AND TREATMENT

LLOYD H. MOUSEL, M.D.
ROCHESTER, MINN.

The prevention and treatment of postoperative atelectasis are of great concern to all anesthetists, for proper management of the patient during and immediately following anesthesia in many instances probably will prevent the occurrence of such a catastrophe. Mismanagement in certain cases undoubtedly is responsible for the development of atelectasis following anesthesia.

Many theories have been advanced as to the etiologic factors involved in the production of atelectasis.¹ It has been suggested that edema of the mucous membranes, similar to angioneurotic edema, might produce enough obstruction to cause pulmonary collapse. Bronchial spasm has been suggested as a possible cause of atelectasis, but this hypothesis seems unlikely because bronchial spasm usually produces the antithetic condition; that is, emphysema with bilateral distribution. The "vasomotor theory" suggests that dilatation and stasis in the blood vessels might produce obstruction in the bronchioles by an outpouring of secretion. It is my opinion that most instances of postoperative atelectasis are caused by mechanical obstruction; that is, actual plugging of a bronchus or several bronchi by tenacious secretions which have been collected in the

tracheobronchial tree during anesthesia, by mucopurulent material which was present preoperatively, or by mucus, blood or vomitus which has been aspirated into the trachea either during or immediately following anesthesia.²

The onset of actual atelectasis probably is gradual. The bronchus becomes plugged, causing preliminary emphysema. If this plug is not removed by aspiration or if the patient is unable to remove the plug by coughing or by change of position, the air in the involved region will be slowly absorbed in the blood stream until pulmonary collapse is complete.³

The symptoms of and observations made concerning postoperative atelectasis usually follow a rather definite pattern. The patient complains of dyspnea, which frequently is out of proportion to the degree of pulmonary involvement present. There is usually a sense of discomfort over the lung involved, the pulse becomes rapid, there is a sudden increase in temperature and cyanosis becomes apparent, the degree of cyanosis depending on the amount of pulmonary tissue involved, and breath sounds become diminished or absent. In the presence of massive atelectasis the heart and mediastinal structures are shifted toward the side involved and the respiratory excursion on the affected side becomes diminished.

Many details must be attended to before and during anesthesia as well as postoperatively if the incidence of postoperative atelectasis is to be reduced. Preoperative sedation may have an effect on the development of pulmonary complications. It is a routine procedure for heavy smokers, patients suffering from chronic sinusitis and patients suffering from chronic pulmonary or respiratory infections of any kind to spend considerable time clearing their nasopharynx and tracheobronchial tree of the accumulated secretions immediately after rising from bed. Heavy smokers almost always have tenacious mucus in their air passages. Patients who receive a sedative in the evening often awaken in the morning in somewhat of a stuporous condition. Their reflexes have been dulled by the action of the sedative. Additional sedatives are usually administered early in the morning, and the patient again drifts off into a restful sleep. As a result he has had no chance or urge to clear his airway of the secretions which have accumulated during the night. It might be well to place the patient in a vertical position and encourage him to clear his nasopharynx and tracheobronchial tree before the sedative is administered in the morning. In this way much offending material might be removed.⁴ The use of atropine or scopolamine reduces the amount of salivary secretion during induction of anesthesia and no doubt makes possible a much smoother induction than could be obtained had not such drugs been administered. However, it is possible that these drugs may be responsible for the drying of secretions which are present until they become so tenacious that the ciliated epitheliums are unable to move them up into the trachea. It is important to have a patient's stomach empty and to be sure that no loose teeth or foreign bodies are present in the patient's mouth, for the aspiration of any foreign body is almost sure to produce atelectasis. Obstruction of any kind to the airway should be relieved

3. Faulkner, W. B., Jr., and Faulkner, E. C.: Postoperative Massive Collapse of the Lung: Its Cause, Prevention and Treatment, Northwest Med. 32: 87-92 (March) 1933. Glickman, L. G., and Minsky, A. A.: Postoperative Massive Pulmonary Collapse, M. Bull. Vet. Admin. 15: 415-417 (April) 1939.

4. Mousel, L. H.: Unpublished data.

immediately, for if obstruction is allowed to remain for any length of time the decreased intrapulmonary pressure on inspiration may cause extravasation of fluids into the alveoli and bronchi.⁵ After the obstruction has been relieved, it might be well to have the patient breathe the anesthetic gases against 6 or 7 cm. of water

Fig. 1 (case 1).—*a*, massive collapse of the right lung with a shifting of heart and mediastinal structures to the affected side; *b*, appearance four hours after bronchoscopic aspiration.

pressure for a few minutes to relieve any edema which might have occurred during the period of obstruction.⁵

If the patient has any amount of secretion in the airway at the termination of anesthesia or if he has vomited during anesthesia and the material has been drawn into the lungs, before he is returned to his room the pharynx, trachea and bronchi should be well aspirated. It is probably best to do the tracheo-bronchial aspiration by the direct vision method through a bronchoscope so that each separate lobe bronchus can be visualized and cleaned of any foreign material. After the patient has been returned to his room, the inhalation of 5 or 10 per cent carbon dioxide and oxygen at hourly intervals often will expand the lobe of the lung which has been collapsed. However, this method does not always produce the results desired, for it may pull a plug of mucus or foreign material deeper into the bronchus.

Morphine and other sedatives should be used sparingly during the first few hours following anesthesia, so that the patient's reflexes may return to as near the normal state as possible. The patient should be turned frequently in bed and encouraged to breathe deeply and to cough. If atelectasis does occur postoperatively, the bronchial obstruction should be removed as soon as the condition has been recognized, for if atelectasis is allowed to exist for many hours secondary pneumonitis or pulmonary suppuration is likely to develop. It is obvious that the ordinary methods of treating atelectasis, such as the patient's inhalation of carbon dioxide and oxygen, frequent turning of the patient and coughing are not likely to relieve the condition if these procedures have been carried out in an attempt to prevent atelectasis from developing. The throat of the patient should be well cocaineized by means of the application of pledgets of cotton carrying a freshly made 20 per cent solution of cocaine. The pledgets should be pressed between the fingers to remove the excess solution of cocaine before they are placed in the pyriform fossa. One pledget carrying cocaine should be passed and held directly between the vocal cords for a few seconds before the bronchoscope is passed. After cocaineization

of the throat has been completed, the bronchoscope usually can be passed without difficulty. Each lobe bronchus should be visualized and all foreign material aspirated from it. Following bronchoscopy, the administration of oxygen or carbon dioxide and oxygen is continued. The patient should be turned from side to side frequently and he should be encouraged to cough.

REPORT OF CASES

CASE 1.—There was nothing unusual in the clinical history of a woman aged 26 with the exception of chronic infection of the upper part of the respiratory tract. Appendectomy and cauterization of the cervix were done under nitrous oxide-oxygen and ether anesthesia. Anesthesia was uneventful. Twelve hours after operation the patient began to cough. Some musical inspiratory rales were heard over the thorax, but the thorax was resonant throughout. Twenty-four hours after operation the patient complained of "lower chest pain" referred through to the back. At this time there were distant breath sounds on the right, and the entire right side of the thorax was dull to percussion. Some bronchial breathing could be heard over the upper third portion of the right lung. The temperature at this time was 98.5 F. The patient became cyanotic. Roentgenologic examination of the thorax showed massive atelectasis of the right lung (fig. 1 *a*). The patient was turned frequently from side to side, 5 per cent carbon dioxide in oxygen was administered at hourly intervals, and she was encouraged to cough. Cyanosis persisted and on the second postoperative day the patient's temperature was 101.4 F.; massive atelectasis was still present. Bronchoscope examination disclosed an inflammatory reaction to be situated around the right middle and lower lobe bronchi. A small amount of thick, tenacious mucus was aspirated from the right middle and lower lobe bronchi. The lower lobe bronchus was edematous and almost completely closed. Gentle dilation was carried out. Following dilation of the edematous tissue a small, tenacious mucous plug could be seen. This mucus was removed by aspiration. Four hours after bronchoscopy there was no dullness over the right side of the thorax. Fourteen hours after bronchoscopy there was evidence of consolidation in the right lower lobe; however, this condition rapidly disappeared and on the fifth postoperative day the thorax was clear and the body temperature receded to normal. Convalescence was uneventful. It was interesting to note the ball-valve action of the mucous plug which was found distal to the edematous mucous membrane in the right lower lobe bronchus, for, following aspiration, the atelectasis apparently completely disappeared, but it was found to be present again

Fig. 2 (case 2).—*a*, atelectasis of the right lower lobe; *b*, complete aeration of the right lower lobe ten hours after bronchoscopic aspiration.

fourteen hours after aspiration. I assume that the edema continued to obstruct the bronchus after aspiration and atelectasis once more developed in the right lower lobe. However, the irritating mucous plug had been removed, so that the edema soon subsided and the lobe once more became filled with air (fig. 1 *b*).²

CASE 2.—An obese woman aged 31 had a slight cough on admission to the hospital. Cholecystectomy was done under nitrous oxide-oxygen, carbon dioxide and ether anesthesia.

Anesthesia was uneventful. Twenty-four hours after operation the patient had a chill which lasted five minutes. She complained of pain in the right lower portion of her thorax. There were decreased breath sounds and decreased resonance over the base of the right lung. Her temperature was 100.6 F. Roentgenologic examination of the thorax showed atelectasis to be present in the right lower lobe (fig. 2a). The patient was submitted to bronchoscopy immediately. The right lower lobe bronchus was completely plugged with very tenacious glistening white mucus. The right middle lobe bronchus contained some mucus. The membrane of the entire right main bronchus appeared to be inflamed. There was no visible edema. The mucus was aspirated and the patient was sent back to her room. A half hour after aspiration the patient stated that she felt much better, and there were no physical signs of atelectasis at this time. Roentgenologic examination of the thorax on the following morning showed the right lower lobe to be completely aerated (fig. 2b). The patient continued to have a productive cough for several days; otherwise, convalescence was uneventful.²

CASE 3.—A man aged 41 came to operation with a diagnosis of right hydronephrosis. Urethronephrostomy and nephrostomy were done under spinal and pentothal sodium anesthesia. Twenty-four hours following anesthesia the patient became somewhat dyspneic and there were decreased breath sounds at the base of the left lung. Inhalations of carbon dioxide and oxygen were administered every half hour. The patient

Fig. 3 (case 3).—a, atelectasis of left lower lobe with elevation of diaphragm and shifting of mediastinum; b, complete aeration of left lower lobe following bronchoscopy.

was turned frequently in bed and was encouraged to cough. Forty-eight hours after anesthesia the patient became cyanotic, the body temperature suddenly increased to 103.2 F., the pulse rate was 124 beats per minute and respiration was 30 per minute. Roentgenologic examination of the thorax showed mediastinal shift and elevation of the diaphragm of the involved side with some fogging of the costophrenic angle on the left (fig. 3a). The patient underwent bronchoscopy, topical anesthesia being used. A large amount of very thick tenacious green mucus was aspirated from the left main bronchus and left lower lobe bronchus. Mild bronchitis was present on the left. The patient was relieved of symptoms immediately following bronchoscopic aspiration. Eighteen hours following aspiration the body temperature was 98.6 F. and remained near that figure; respiration and pulse were decreased within normal limits. Roentgenologic examination of the thorax showed it to be clear (fig. 3b).

CASE 4.—A woman aged 44 came to operation because of a stone in the left kidney. Pelvolithotomy was done under spinal anesthesia. Forty-eight hours after operation the patient complained of pain in the right portion of the thorax near the sternum. The respiratory rate was 34 per minute and respiration was grunting in character. The temperature suddenly increased to 102.8 F., the pulse rate 135 per minute. The patient became dyspneic and somewhat cyanotic. She had been coughing up some amount of sputum since operation. The usual measures had been carried out in an attempt to prevent atelectasis from developing. On physical examination breath sounds were found to be greatly diminished over the entire right side of the thorax. Roentgenologic examination

of the thorax confirmed the diagnosis of pulmonary atelectasis on the right (fig. 4a). The patient underwent bronchoscopy under topical anesthesia. The right main bronchus was found to contain at least 1 tablespoon of thick mucopurulent material. Severe bronchitis was present on the right. Rather marked edema of the right lower lobe bronchus was noted. All visible mucus was removed by aspiration. At the time of bronchoscopy

Fig. 4 (case 4).—a, massive atelectasis of the right lung with shift of mediastinum; b, aeration of entire right lung.

I doubted if this patient would derive much benefit from the procedure of aspiration, for the inflammatory reaction was so marked that it appeared that pneumonia was certain to develop. Within a few minutes following bronchoscopy the breath sounds were coming through in a normal manner over the entire right lung. The patient felt much better and the temperature and pulse rate both decreased rapidly. Twelve hours following bronchoscopic aspiration the results of roentgenologic examination of the thorax were negative for atelectasis (fig. 4b). The body temperature was 97.8 F., pulse rate 100 and respiration 20 per minute. Recovery of the patient was uneventful.

CASE 5.—A man aged 48 was submitted to cholecystectomy, choledochostomy and appendectomy. The operation was done under nitrous oxide, carbon dioxide and ether anesthesia. Twenty-four hours after operation the patient complained of pain on inspiration. The breath sounds were decreased over the base of the right lung. Routine inhalations of carbon dioxide and oxygen with frequent moving of the patient in bed were started at this time. Twelve hours later there was a progression of symptoms. Rhonchi could be heard over both lungs. The patient began coughing up bloody sputum. Cyanosis grade 2 was present. The patient was placed in an oxygen tent and improvement resulted almost immediately. On the

Fig. 5 (case 5).—a, atelectasis of entire right lung; b, aeration of right lung, residual bronchial pneumonia.

third postoperative day the patient became much worse and cyanosis was present in spite of the oxygen which was being administered. The temperature rose to 101.5 F., pulse 100 per minute and respiration 25 per minute. A diagnosis of atelectasis of the right lung was made (fig. 5a). The patient underwent bronchoscopy under topical anesthesia. A fairly large amount of mucopurulent material was removed from the right main bronchus and a small amount of purulent material was taken from the left main bronchus. Immediately following broncho-

scopic aspiration the patient looked and felt much better. The breath sounds were coming through over the base of the right lung at this time. A roentgenogram of the thorax taken immediately following bronchoscopy showed marked improvement (fig. 5b). The body temperature dropped to 99.8 F., the pulse rate was 76 and the respiratory rate 18 per minute within a short time after bronchoscopy. Inhalation of carbon dioxide and oxygen and frequent turning of the patient were resumed. Low grade bronchial pneumonia was treated; otherwise convalescence of the patient was uneventful.

CONCLUSIONS

1. Much can be done by the anesthetist toward preventing postoperative atelectasis.
2. Patients who have aspirated vomitus or who have an accumulation of mucus, blood or other material in the trachea at the termination of anesthesia should be submitted to tracheobronchial aspiration before leaving the operating table. The bronchoscope can usually be passed without difficulty if it is done before the patient has recovered from the anesthetic.
3. Postoperative atelectasis can be successfully treated in most instances by bronchoscopic aspiration.
4. Bronchoscopic aspiration should be carried out as soon as possible after the diagnosis is made in order to prevent pneumonitis or pulmonary suppuration.

ABSTRACT OF DISCUSSION

DR. URBAN H. EVERSOLE, Boston: The aspiration of fluid from the respiratory passages for the prevention and treatment of pulmonary complications due to atelectasis cannot be overemphasized. Unfortunately, bronchoscopy has too often been looked on as a hazardous procedure to which a seriously ill patient should not be submitted. I have become convinced that it is not a hazardous procedure. All patients who have demonstrated their inability to reexpand a collapsed portion of the lung spontaneously or to raise fluid which has accumulated in the tracheobronchial tree should immediately be submitted to this procedure. There are many patients who have evidence of a large amount of fluid in the tracheobronchial tree which they are unable to raise spontaneously but who do not have evidence of definite areas of atelectasis. Simple aspiration of this fluid through a number 22 French urethral catheter is frequently all that is necessary. This procedure may be carried out after spraying the pharynx with cocaine. The catheter can best be introduced through the nose and guided into the larynx by means of forceps under direct vision through a laryngoscope. There is another group of patients in which I have found suction bronchoscopy of great value. These are patients suffering from suppurative pulmonary disease such as bronchiectasis or lung abscess. Even though these patients may have been treated by postural drainage for long periods of time, the induction of general anesthesia may result in the release into the larger air passages of large quantities of fluid. This release of fluid may be quite early in the induction and before there is sufficient relaxation for an intratracheal tube to be introduced with facility, through which fluid can be aspirated. This fluid may constitute a real danger to the patient's life, as he may actually drown in it. Even if this fluid is not released in amounts large enough to endanger the patient's life from drowning, it may result in a spread of the infection. I have adopted the following routine: 1. The patient is brought to the operating room and under cocaine topical anesthesia a thorough aspiration of the respiratory passages through a bronchoscope is performed. 2. The bronchoscope is removed and an intratracheal tube is immediately inserted while the patient is still awake. 3. General anesthesia is now induced with the intratracheal tube in place. Fluid that may accumulate during the course of the operation can be aspirated through the intratracheal tube by means of a urethral catheter. 4. Immediately after the operation is ended a thorough aspiration of the tracheobronchial tree is again carried out through a bronchoscope while the patient is still under general anesthesia. 5. During the course of their convalescence these

patients are submitted to suction bronchoscopy as often as there is evidence of fluid accumulation which they are unable to raise themselves.

DR. HERMAN J. MOERSCH, Rochester, Minn.: Dr. Mouse's presentation is valuable and timely. He has emphasized the importance of postoperative pulmonary complications and the important role the anesthetist should play in the prevention, the diagnosis and the treatment of postoperative pulmonary complications. Postoperative pulmonary complications may occur in about 10 per cent of patients who undergo operation on the stomach and duodenum, and in about 4 per cent of those who undergo operation on the lower part of the abdomen. Massive atelectasis of the lung was first described by Pasteur in 1890, but scant attention in this country was paid to its importance until after the first World War. Its great importance in relation to postoperative pneumonia is now appreciated. The hypothesis most generally accepted is that which postulates that postoperative pulmonary atelectasis occurs as a result of obstruction of the bronchus due to aspiration of material into the bronchus in the course of the operation, or retention in the bronchi of secretions which normally are expelled. Support for this hypothesis is given in the studies of Gray, who found that he could reduce the incidence of postoperative pulmonary complications by about 30 per cent simply by placing the patient in the Trendelenburg position after operation. It is my opinion that, if it was possible for the patient to leave the operating room with a so-called dry lung and to remain in that condition until the cough reflex returns, we could eliminate almost entirely postoperative pneumonia. There are many methods which can be employed in the treatment of postoperative atelectasis. Among them bronchoscopy holds a very important position, as it permits the aspiration of retained secretions the presence of which in the bronchial tree produces the atelectasis. There may be some difference of opinion as to who should carry out the bronchoscopic aspiration when indicated after operation. The ideal arrangement would be to have a skilled bronchoscopist available at all times, but this is not always possible. When a skilled bronchoscopist is not available, the anesthetist, if he has had proper training in the procedure of bronchoscopy, is in a very favorable position to carry out the procedure, for no one follows the course of the patient more closely than the anesthetist during and immediately after operation. By such an arrangement I am sure that many a life that otherwise might be lost because of postoperative pneumonia would be saved.

DR. F. ELMORE HUBBARD, Montclair, N. J.: I should like to ask what type of bronchoscope the doctor has recommended.

DR. LLOYD H. MOUSEL, Rochester, Minn.: I am glad that Dr. Eversole mentioned suction through a soft rubber catheter. This procedure can be carried out satisfactorily in many instances, particularly if an intratracheal tube is in place. If a bronchoscope is not available, suction through a catheter should then be carried out in an attempt to remove all foreign material from the tracheobronchial tree. Aspiration through a bronchoscope gives the anesthetist the advantage of being able to visualize each separate lobe bronchus and leaves nothing to chance. Foreign material or mucus then can be aspirated from each separate lobe bronchus. I use a Negus bronchoscope because I received my training with that particular instrument. The Negus bronchoscope has the advantage of having both proximal and distal lighting. There are several good bronchoscopes on the market. Any of them should be satisfactory.

Mental Factors.—The commonest mental factors derived from the immediate environment are financial and business worries, domestic difficulties, dissatisfactions of all kinds, disappointments and worries in the sexual sphere and deaths of relatives. It is such situations as these that the individual, especially the susceptible individual, finds it difficult to face. He may surmount one difficulty successfully only to go down before an accumulation of troubles. It is not the situation itself that matters, but what the subject feels about it.—Henderson, D. K., and Gillespie, R. D.: *A Text-Book of Psychiatry for Students and Practitioners*, London, Oxford University Press, 1940.

THE MENTAL HYGIENE ASPECT OF
THE TRAFFIC ACCIDENT

LOWELL S. SELLING, M.D., Ph.D., Dr.P.H.

DETROIT

In 1937 motor vehicle accidents were ninth in the list of ten principal causes of death in the United States. In spite of this, public health authorities have not given this cause of death as much attention as they have to others. When one realizes that in that year 39,643 persons died in highway accidents¹—a mortality rate of 30.7 per cent—one must admit that if public health authorities, psychiatrists and others interested in the medical aspect of life and death can take any part in the solution of the traffic accident problem it is their duty to do so.

One can emphasize this even more definitely by pointing out that among persons in the youth range, from 5 to 19 years of age, in 1937 motor vehicle accidents were the second highest cause of death,² and that in 1939, while the death rate decreased, resulting in only 32,100 deaths, the number of persons injured was appallingly large, 1,210,200.³

One reason, undoubtedly, why health departments and mental hygiene clinics have not taken an active interest in attempting to control this phase of mortality and morbidity is that the work seemingly is being fairly well done by other agencies. Whereas the health departments collect statistics through birth and death certificates, the police departments, with their accident investigators, not only are able to determine the fact that a victim died or was injured but can secure all of the accompanying data that might be used to educate the public or to point out the need for specific engineering changes on the highway. The material for the selection of such data is not in the hands of health departments, and it need not be, for it is frequently necessary to make arrests at the scene of the accident, which is the duty of the police and not of the health authorities.

In spite of the fact that the Psychopathic Clinic of the Recorder's Court has been actively engaged in studying traffic offenders since August 1921 and, in 1929, reported the psychiatric observations in a group of 100 cases,⁴ the attention of psychiatrists and public health authorities has not been extensively directed toward the traffic problem.

While there are, perhaps, a half dozen psychologists with scientific training directed toward the analysis of human mental processes, too few experts who are medically trained along the same line, that is, psychiatrists, have taken an interest in this problem; yet it is undoubtedly true that physicians practicing in mental hospitals and mental clinics frequently have the traffic angle of their cases brought directly to their attention. But the treatment and correction of the traffic problem through psychiatric means are not in the minds of most psychiatrists, since their practice in clinics and hospitals is overshadowed by the problem

of correcting the ailment rather than of considering the ailing person in the light of a potential traffic menace.

THE PLACE OF MENTAL HYGIENE

The question must be raised of how much of a role mental hygiene can play in the prevention of traffic accidents. In analyzing statistics with regard to the causes of death one finds, for instance, that it is not the inexperienced driver who gets into trouble, for 95 per cent of operators involved in accidents in 1939 had had a year or more of experience in driving an automobile.⁴ Eighty-five per cent of accidents occurred on clear dry days⁵ and in 77 per cent of cases the pavement was dry,⁶ so that weather does not play a predominating part. Seventy-six per cent of the cars were going straight when involved in the accident;⁷ 35 per cent of the accidents occurred between intersections and 13 per cent on the straight highway.⁸ On this basis one cannot emphasize engineering as being to blame, for the engineers have provided straight safe highways.

The question of mechanical failure of the car is often brought up. It must be admitted that statistics on this subject are poor, since an automobile which is involved in an accident sufficiently serious to be reported is usually thrown out of adjustment in many ways so that a test of the car after the accident does not give accurate information as to its condition previous to the accident. The assumption was made in a report in 1937 by the Michigan State Police, covering a two months period, that only about 2 or 3 per cent of accidents could be ascribed to mechanical failure of the car. I myself believe that this percentage is too high because a great number of cars, even new ones, may be out of optimal adjustment at any given time, but the apt and careful driver learns to compensate quickly and mechanically for these changes in adjustment, and, although he has the trouble rectified as soon as possible, many cars which are not in good adjustment are on the streets but are never involved in accidents.

This throws the problem directly back on the human element. Pedestrians account for 38.9 per cent of deaths and 24.3 per cent of injuries as a result of traffic accidents. The pedestrian in many instances, was more to blame than the driver, which emphasizes the fact that the human element remains important whether the person at fault is the pedestrian or the driver.

It is, of course, much easier to prescribe therapy for the driver because he must be licensed and, as in Detroit, may have to be examined as a part of the licensing procedure or as part of the evaluation of his guilt if he commits a traffic offense. Pedestrians—except in cases of fatal accident in which an autopsy is done—cannot be subjected to physical, and certainly not to mental, study.

Nevertheless, it is known that alcoholism plays an important part in pedestrian deaths and that physical failure due to age or illness is also important. Pedestrian control is as important an aspect of the psychology prevention of traffic accidents as is driver control.

On the basis of all the previously presented facts, I should be inclined to eliminate the engineering aspect of accidents and to consider the two current therapies of enforcement and education as being closely associated with mental hygiene. The rationale which lies

behind proper enforcement cannot be considered in great detail here. Police procedures, through long devolution, became more or less indifferent toward the physical and mental aspects of the offender until the establishment of criminologic clinics during the past quarter of a century. Even now the clinical aspect is a minor consideration in enforcement, and the individual as a mental health problem does not exist for the policeman who has a routine to follow and whose effectiveness is determined more or less by the number of arrests he can make and the assurance in any community that a violation will be followed by a sure arrest. In other words, in enforcement the mechanism of fear is emphasized, and, while fear has its therapeutic uses, the application of it by the police perhaps engenders other emotions which eventually defeat the purpose of strict enforcement.

It must be admitted that traffic officers in most large cities are given a certain amount of leeway in their power of arrest and can give warnings and advice. The value of such warning and advice must rest on the personality of the officer and his individual insight, and of course, since there is such a plethora of policemen, the range of therapeutic aptitude must be extremely broad.

MENTAL HYGIENE METHODS

The problem, then, rests directly with mental hygiene, and the mental hygiene approaches are twofold: educational and clinical.

Most public health education springs from one of the central public health agencies or, in the larger cities, from the departments of health themselves. The methods of publicity and procedures similar to those used in health education are frequently utilized by the police and by private agencies, such as automobile clubs and insurance companies, in education in accident prevention.

I feel that radio and newspaper education along safety lines are superior in some ways to those which have been invoked in the past by smaller health agencies for disease control. There are, of course, more funds available from insurance companies and their ilk than from municipal fiscal authorities. This would make a difference in preparing an interesting radio program. When there can be a little insurance advertising, commercial firms with funds can pay for better hours on the air and better prepared programs.

I made a simple survey of the situation in Detroit. I found that practically every type of educational facility which is mentioned as being of value in health education is being applied to the safety problem. There is, of course, some incoordination because of the fact that each sponsor of a radio program and each municipal department has its own ideas—often inept and amateurish—of how results are to be obtained. Data submitted over the air are not based on scientific study, and the attention of the listener is directed toward what the individual agency considers advisable rather than toward what might be uniformly considered a good procedure. By that I mean that on one day there may be a radio talk from one station dealing with speeding which flatly advises against driving over a certain rate, while the next day another station may discuss the *prima facie* speed limit which permits persons to evade the speeding laws by virtue of the fact that, when no lives are endangered, speed need not be limited.

This is different from health education work, which in Michigan is being done by a centralized council in

which all radio and at least one newspaper production, no matter on what medical subject, are submitted to committees of the local and state health agencies.

In Detroit the following traffic educational programs were employed during May 1940: On the five principal radio stations a series of talks was presented once a week; the police department had charge of this; in addition, there was an entertainment program by the local motor club which contained safety advice; the two leading Detroit newspapers carried a safety cartoon once a week, and occasionally such a cartoon appeared oftener than that. There is no safety dramatic radio program at the present time or any continued safety educational column like that of Logan Clendening in the field of medicine. The foreign language newspapers are not being systematically used, although 35 per cent of the patients coming through the clinic are foreign language speaking. There is a poster campaign in English on the street cars and busses advising the pedestrian; these posters are produced by the Detroit Industrial Safety Council, which, it might be said, by means of campaigns has vastly cut down the number of traffic accidents among employees of the various industrial plants in the city. These employees have even reduced their accident records when not driving plant vehicles. There is, however, nothing except this poster campaign directed toward the pedestrian.

There is but little active campaigning directed against the drunken driver in the sense of preventing him from drinking and driving. There is much newspaper talk but little tendency toward the psychiatric control of drinking. If drinking, at least excessive drinking, is an escape mechanism, that mechanism must have a basis in some problem from which the person desires to escape. Such problems must be solved clinically by a lawyer, a physician or, more properly, a psychiatrist. The amount of psychiatric help needed for drinkers is obviously great when one realizes that 7.3 per cent of the drivers involved in accidents in 1937 had been drinking and that 12.9 per cent of the pedestrians killed in that year had also been drinking.⁹ This offers a serious problem, which is not to be solved by the mere creation of apparatus for determining the amount of alcohol in the body fluids of the driver in order to obtain a conviction for drunken driving.

If a man is chronically alcoholic, at least from a psychiatric standpoint, punishment will not keep him from drinking. Of course, a second conviction of drunken driving in Michigan makes it mandatory that his license be revoked, so that he can no longer drive. Most of the drunken drivers who have been referred to the Psychopathic Clinic have had but little consumption of alcohol at the time of the offense, but rather have taken a small amount on an empty stomach when under tension, resulting in a more serious situation than the abnormal imbibition of the heavy drinker, which causes him to lose consciousness or makes his behavior so obviously incompetent that his friends will not permit him to drive.

THE CLINICAL APPROACH

The next phase of accident prevention from the psychiatric standpoint rests in the hands of clinics. The usual procedures of mental hygiene clinics are on the whole applicable to the driver, but we at the clinic have found that special standards and additional examination processes are necessary. As an example, in the case of a refractive disorder of the eyes it is

⁹ Death Begins at 40, Hartford, Conn., Travelers Insurance Company, page 11.

known that significant eyestrain or difficulty in reading print occurs in children at a certain level, presumably about 20/50 in each eye. To carry this problem of acuity of near vision over into traffic would be manifestly unfair because traffic is a far vision problem. Some standards set up at the present time on the basis of visual deficiency in reading must still be open to question when applied to traffic.

From the standpoint of mental hygiene we have no standards except that we recognize that psychotic and feeble-minded persons should not drive. It is manifestly impossible to make a psychiatric examination of all candidates for a driver's license—the expense in money and time would be prohibitive.

In Detroit a system has been worked out by the police department which to some extent solves the problem. When a person is adjudged insane in the probate court, a record of this adjudication is sent to the secretary of state's office in the state capitol and the psychotic person's license is revoked. All candidates coming before the licensing examiners of the Detroit police department have their records checked with the psychologic clinic of the board of education, and those who have been diagnosed as feeble-minded are, as a rule, refused a driver's license. Where the deadline should be drawn in a case of this sort, i. e. under what conditions a person with borderline feeble-mindedness should be permitted to drive, is still a question. The answer in this type of problem seems to be individual clinical examination by trained examiners.

Some sort of screening process is necessary to make the best use of clinics, because in our experience a thorough survey of a driver is not possible in less than four hours. Many of the stupid or extremely maladjusted persons who come into the clinic require over a day, which would mean eight hours or more for examination. Our examination consists of the usual mental hygiene procedures of a physical examination, application of the proper psychologic tests, taking the social history and coordinating all of these with a psychiatric examination. In addition, for the mechanical problems of traffic we have had to devise and adapt a number of aptitude tests for reaction time, judgment of speed and distance, color blindness and knowledge of traffic laws, as well as other traits which need no enumeration here.

Each one of these special procedures is of importance; even the physical examination beyond obvious capacity to show organic competence to manipulate car controls is of value from the mental hygiene point of view. A case was brought to our attention characterized by extremely aggressive behavior on the part of a driver. He had a tendency to speed, to cut in and out of traffic and to fail to stop at stop streets. The physical examination revealed that he had had encephalitis and at the present time presented an obvious parkinsonian syndrome. On actual mechanical aptitude tests he was not so retarded that under ordinary conditions he would not be a safe driver, but his whole attitude indicated a compensatory reaction because of his rejection by girls. His problems in other spheres brought forcibly to our attention that it was not the crippling effect of the disease but its effect on the patient's mentality and his attitude that was of greater importance.

The social history in the case of a traffic offender is of great value. Careful analysis of reckless drivers, of whom we see a great many, directly reveals to us some basic reasons for drivers getting into trouble.

For instance, the boy who is suppressed by his parents and is not allowed to drive until he can get a license of his own volition borrows the cars of others and drives madly. One cause of such behavior is bravado, to show his parents that he can do things contrary to their beliefs.

Almost every phase of the social history—childhood, schooling, occupational adjustment, marital and sexual relations and recreational habits—may have a bearing on the person's attitude toward driving. For example, it is not infrequent to have a man who is browbeaten by his wife—evidence of which comes out in the marital part of the history—become very aggressive when behind the wheel of a high powered vehicle, when he is, of course, dangerous.

The psychologic and psychiatric examinations are of great importance. When intelligence is rated below a certain level (I do not feel competent to give a definite level of the intelligence quotient at which this occurs), a driver is obviously not competent to drive no matter how well he may react mechanically. His judgment in an emergency has a much greater chance of being faulty than in the case of a normal person. In addition, we find that feeble-minded persons have a much more antisocial attitude, owing to the fact that they are not able to note and assimilate in as efficient a fashion the reactions of others toward antisocial types of behavior. The attitude of an aggressive and dangerous driver may be caused by a certain inward mechanism, such as that described in the case of the subdued boy previously mentioned. Probably all young persons are aggressive and egocentric drivers, and only as they grow older are they able to comprehend the sociologic factors impinging on them which tend to mold this juvenile behavior into acceptable adult conduct.

In a previous paper¹⁰ I cited cases of neurotic individuals who had compulsive tendencies to injure and maim father substitutes or persons challenging their egos. The same development of complex material which causes the neurosis may lie behind various kinds of traffic offenses; the man who has a deep oedipus complex may attempt to run down men in a safety zone because these men are father substitutes. This is particularly true in the case of policemen, who are definitely a symbol for law as manifested by the father. The anxiety neurosis has a somewhat similar cause, but the manifestation of the psychodynamics of the traffic offender with such a neurosis is likely to cause accidents because of his brooding, worries, distractibility and inadequate interest in the task at hand—driving. So individuals with a major neurosis should not be permitted to drive. On the other hand, since neuroses, as a rule, are curable, particularly in those cases in which medical help can be secured, such sufferers may, after a series of psychiatric treatments, be restored to the road.

The psychotic drivers have already been mentioned. It is obvious that no psychotic person should drive, but the presence of the condition can be elicited only by a psychiatric examination. In our experience with a highly selected group of more than a thousand offenders, about 4 per cent were found to be psychotic. Of course, since these persons were referred to us because of their bizarre conduct in court or at the time of arrest, the percentage is higher than that found in a random sample of the driving population.

10. Selling, Lowell S.: The Psychiatric Findings in the Cases of Five Hundred Traffic Offenders and Accident-Prone Drivers, *Am. J. Psychiat.* 97: 68-79 (July) 1940.

CONCLUSION

Although the general educational procedures and clinical method of attacking traffic problems offer an obvious approach for mental hygiene, one can expect in the future to see the attack on the abnormal personalities expanded. With the increased development of school medicine and psychologic clinics attached to schools, there can be no valid reason for not detecting those who are physically and mentally incompetent to drive a car before they reach driving age. If they are treatable the process of treatment can be initiated to benefit both the potential driver and the general health of the community.

One obvious method which should be highly worth while is the proper education of the new drivers. It is to be hoped that those children who have gone through the schools and have already had extensive safety education will be better drivers as they reach driving age. With the establishment of formal courses to teach children properly to drive rather than allowing them to learn about driving by trial and error, as the older generations have, one can anticipate even greater success. Mental hygiene will enter into this situation immensely, for the interpersonal reactions of the driver depend on his emotional and mental adjustment toward himself and toward other people, and this, of course, lies in the field of mental hygiene.

To summarize then one can say that, while engineering and enforcement are important approaches to the elimination of traffic accidents, greater need, and perhaps greater hope, lies in the attack on the abnormal personality and in the dissemination of material for normal persons which will tend toward changed attitudes in the matter of driving. Mental hygiene in its aspects of public health education toward better thinking and of preventive psychiatry in the form of clinical treatment of persons with bizarre conduct has already demonstrated in our clinic that it is a useful life saving service.

Whether the basis of the attack on traffic problems should be in health departments of the various communities cannot immediately be determined, but certainly some unification of safety education is called for. In the light of the extensive experiences of health departments, national and local, in the field of health education, these organizations can definitely be considered as fulcrums for a unified and expanded mental health program for drivers.

ABSTRACT OF DISCUSSION

DR. DANIEL BLAIN, New York: There are more deaths due to this one form of accident than from typhoid, smallpox, measles, scarlet fever, whooping cough, diphtheria, erysipelas, meningitis, malaria, rheumatism and syphilis put together. This amounts to a serious epidemic, now chronic for twenty-seven years; yet the medical profession has been singularly uninterested. Faulty cars, alcohol, exhaustion, disease and age play a part. Certain accident-prone drivers are responsible for a large number of accidents. With due deference to all these causes, I should like to suggest the greatest menace to the eventual solution of the problem: the one-accident driver. Figures show that of 4,500,000 accidents of all kinds one third are due to accident-prone drivers. These I think may be said to be ill mentally or physically. That leaves 3,000,000 accidents, 600,000 injuries and 20,000 fatalities a year, presumably due to normal people, people perfectly capable of acting properly, who can see, hear, stop and steer the car but who at one time in all their comings and goings have an accident. This is a real major health problem, one not even scratched by existing plans, one barely mentioned in any publication. It is

the one-accident driver who is the menace because there are so many of him. It is true that education tries to reach people in the mass, but where is the education that deals with people's emotions, their rivalries, competition, instincts, timidity, compulsion drives, absentmindedness, carelessness and, above all else, the deep laid gambling instinct, the willingness to take a chance, the belief in the magic of their own luck, the unwillingness to face the facts of their own chances of crashing sooner or later, the unconscious motive of aggression, revenge, the inner demand to hurry and pass everything, compensation for inferiority, or the Jehovah complex that "I am better than any one else and deserve the whole road," and so on? To conclude, the accident problem narrows down to finding, eliminating and preventing from driving a small group of high accident drivers, and the enormous task of influencing the great public who make up the mass of pedestrians and relatively normal drivers who contribute to the great percentage of accidents.

NEW YORK

In March 1940 the Office of Dermatoses Investigations of the U. S. Public Health Service received a notification from Dr. Donald S. Mitchell, of Montreal, Canada, that there were many cases of dermatitis occurring in Canada on persons wearing cotton fabrics finished with a preparation made by a large American chemical manufacturing company. He asked whether we had a record of such cases occurring in the United States.

The manufacturers of the product were notified and they stated that they had no record of such cases in this country, despite the fact that they had sold it to many finishing factories. They also stated that they had performed patch tests on human beings with the material before they placed it on the market and that they had obtained no reactions. They further stated that the finish as sold by them was diluted with various other chemicals in the factory where the finishing was done before it was applied to the fabric, and they thought that the dermatitis might be caused by one of the chemicals added to the finish by the finishers.

The Office of Dermatoses Investigations requested that the chemical company send samples of their finish (a milky looking emulsion), and these samples were forwarded to Dr. Mitchell for patch testing his patients. He found that even though he diluted the finish with 99 parts of water, a piece of gauze dipped into it gave positive patch tests on his patients. The manufacturer of the finish was then requested to send samples of each of the ingredients used in the finish. Of these ingre-

dients xylene, dupinol (a wetting out agent and emulsifier) and an acid ester gum were suspected as the possible irritants, the other ingredients being inert substances, such as starch. The suspected chemicals were forwarded to Dr. Mitchell, who again patch tested his patients with these substances in the dilution in which they were contained in the finish. He obtained reactions only from the ester gum. Therefore it appears that this was the principal sensitizer in the finish, although traces of xylene remaining in the finish may also have played a part, producing sensitization by aiding the acid ester gum to penetrate the skin.

Ester gums are combinations of natural resins (such as rosin) with glycerin. They can be made by combining rosin with glycerin or directly from a combination of glycerin with the oleo resin. The principal ingredient of rosin is abietic acid, and the degree of neutralization of the abietic acid with the glycerin determines the acid number of the ester gum. Rosin was found to be the chief irritant in adhesive plaster,¹ and it is to be expected that an ester gum with a high acid number (containing uncombined abietic acid) if kept in contact with the skin will cause dermatitis in a manner similar to that caused by adhesive plaster.

While the investigation of the dermatitis in Canada was under way, reports were coming into the Office of Dermatoses Investigations of dermatitis occurring in Missouri and other parts of the United States from "shorts" sold in chain stores. The dermatitis was characterized by intense pruritus and covered most of the skin area touched by the shorts. In some cases the inflammation was so severe as to cause systemic symptoms and required hospitalization. In one case a circumcision was necessary to relieve the edema of the foreskin. A visit to the principal office of one chain store showed that it had put about 30,000 dozen of these shorts into its branch stores, but as soon as it received reports that these were causing dermatitis it recalled all those that were not sold, amounting to about 8,000 dozen. In the meantime it had received forty-eight complaints of dermatitis caused by the shorts, occurring in various parts of the country. Some of these were confirmed by positive patch tests with pieces of the shorts. The shorts consisted of cotton dyed in various combinations and finished. No one combination of colors was involved. The cases of dermatitis occurred from all the colors. An analysis of twenty-seven cases according to color and lot is given in table 1.

Although the dyes in these shorts bled when immersed in water, patch tests on the patients with the dyes and with the fabrics were negative, but patch tests with the finish were positive. Investigations showed that the fabrics in the shorts were all dyed and finished in one finishing plant, and inquiry at this plant revealed that the finish it used was purchased from the same company and was the same finish which caused the dermatitis occurring in Canada. This finish when applied undiluted to the shaved skin of rabbits produced a dermatitis within seventy-two hours.

While this investigation was going on, notice was received from South Carolina that dermatitis was occurring among the girls sewing and handling cotton fabrics manufactured in one of the South Carolina mills. Investigation at this mill showed that these fabrics were also treated with the same finish.

About this time one of us saw a case of generalized dermatitis (fig. 1) which was proved by patch test to have been caused by wearing new pajamas. In this case patch tests performed at different times with the finish extracted from the fabric and applied to a piece of white gauze, and with the finish causing the dermatitis in Canada applied to white gauze, all produced marked reactions and an exacerbation of a generalized dermatitis (figs. 2 and 3). Subsequent investigation revealed that the pajamas were finished with the same finish that caused the dermatitis in Canada.

About the same time reports began coming in of dermatitis occurring among women wearing hosiery made from a new synthetic fiber substitute for silk. The first of these reports was received on May 1 and came in the form of a query from a hosiery mill in Indiana, asking for whatever information the Public Health Service had on this matter. It was told that the finish was suspected and was asked to give the trade name or composition of the finish which it used. Reports of cases of dermatitis from hosiery made of the new synthetic fiber were then received by the Public Health Service from the following sources. All requested whatever information the Public Health Service had as to the actual cause of the dermatitis and

they were all told that the Office of Dermatoses Investigations was investigating the matter and that the results pointed to the finish on the hose as the actual irritant.

On June 22, Dr. Verne K. Harvey, director of the Indiana State Board of Health, reported thirty-eight cases.

On June 24, Dr. Adolph B. Loveman of Louisville, Ky., reported four cases.

On July 15, Dr. Frederick W. Birkman of New York reported one case.

On July 16, Dr. George Van Rhee of Detroit reported one case.

On July 22 Dr. S. J. Fanburg of Newark, N. J., reported four cases.

Investigations in Indiana, where the largest number of cases were reported, showed seventy-four known cases, of which number the authors actually saw sixty-four. In these cases the dermatitis began from two to twenty-eight days after the patient began wearing the stockings. The average case began two days after the stockings were worn. Some of the women wore the hose for only one or two days and then not again for two weeks. In these the dermatitis began within twenty-four hours after the hose were worn a second time. Sensitization in these cases was produced by previously wearing the hose.

The eruption usually began on the lower third and posterior aspect of the thighs as a small, brownish red papule around the hair follicle. It extended rapidly up the thighs to where the stocking ended and down

1. Schwartz, Louis, and Peck, Samuel: The Irritants in Adhesive Plaster, Pub. Health Rep. 50:S11-S19 (June 14) 1935, reprint 1690.

on the leg to the shoe top. In no case did it involve the foot. The pruritus was severe and the skin was erythematous, edematous and covered with brownish red macules and papules. Exposure to sunlight definitely aggravated the dermatitis and pruritus. When the wearing of the hosiery was discontinued, then under palliative, antipruritic treatment and sedatives the eruption faded and finally disappeared, but the pruritus persisted in some of the cases even after seven weeks. The follicles remained enlarged for a number of weeks after the eruption subsided.

Some of the patients developed urticarial and eczematous lesions on the trunk, arms, face, eyes and ears accompanied by such constitutional symptoms as headache, dizziness, elevated temperature, blurred vision, nausea and nervousness. Blood examinations made on

two of the patients showed no significant changes.

Patch tests performed in thirteen of these sixty-four cases with pieces of the hose which were worn gave positive reactions in forty-eight hours. On two of these patients patch tests were performed with the diluted finish used on the hose and in both of them the reactions obtained were severe and the sites of previous patch tests with the hose again became active and the subsiding dermatitis flared up. In addition to this, one of the patients developed a generalized erythema multiforme and the other developed pruritus of the right side of the face and complained of severe pain in her

Fig. 1.—Dermatitis caused by finish on pajamas.

head and blurred vision. Examination of the eyes, however, revealed nothing pathologic. All the patients patch tested showed marked sensitivity to the adhesive plaster.

Some of the patients who had recovered again bought hose made of the new synthetic silk but having a different finish, and they have continued wearing them without ill effects.

It was suspected by the Public Health Service that this outbreak of dermatitis from wearing the hose was caused by the same finish which caused the dermatitis from wearing cotton fabrics, and the investigation to discover the actual cause of these cases was undertaken.

The factory where the new synthetic thread is made was visited and the manufacturing process studied. The new synthetic fiber is a polymer made from hexamethylenediamine and adipic acid. It enters the plant in the form of the monomer, a water white solution in

water. That the monomer is not a primary skin irritant is shown by the fact that the hands of one of us was immersed in it and allowed to dry, with no after-effects. The monomer is mixed with an inert delustering agent and an organic acid stabilizer and under heat and pressure is converted into the polymer. During the process of polymerization fugitive irritating compounds may be formed which appear for a short time in the unfinished fiber. They are said to disappear from the fiber during the remainder of the manufacturing process. The polymer, a milky white solid, is dried and cut into small chips. These chips are melted by heat and forced through minute openings to form a thread. The thread is cooled and solidified and a number of the fine threads are wetted with an emulsion and twisted into one thread. This emulsion consists of a vegetable oil, an organic solvent, a soap and an essential oil. There is only a fraction of 1 per cent by weight of the emulsion on the thread.

The thread is now stretched and twisted and then spooled. It is sold in this form but requires to be "thrown" before it can be used for knitting. Some of the thread is covered with a sizing consisting of a mixture of a polyvinyl compound and an innocuous hardening agent. It is then dried and oiled with a vegetable oil and wound on cones. These cones are sold to the hosiery mills and can be knitted without being "thrown."

The oil mixtures and sizing applied to the thread in the process of manufacture are supposedly removed in the hosiery mill by the "boil-off" operation. If the "boil-off" is imperfect, some of these oils and sizing may be left on the fiber and cause dermatitis in sensitive individuals.

It is a matter of record that, before the new synthetic fiber was put into large production, patch tests were performed with the unfinished thread on 200 people, with rayon and natural degummed silk as a control, and there were no greater number of positive reactions to the new synthetic fiber than to the control fabrics. In addition to this many thousand pairs of unfinished hose made of the new synthetic thread were given away for trial wear before it was placed on the market, and no cases of dermatitis occurred on the wearers. Samples of the new synthetic fiber in the various stages of manufacture were obtained at the factory for patch testing.

The state of Indiana, where the most cases of dermatitis were reported, was next visited. It was found that in all the confirmed cases of dermatitis hose manufactured in one mill had been worn. This was the mill which on May 1 reported the occurrence of cases to the Public Health Service. Chemical examination of thirty-six pairs of hose which had caused dermatitis on thirty patients showed that thirty-two pairs were made at this one mill and were all finished with the same finish. The other four pairs had been washed and there was not sufficient finish remaining on them to enable identification by chemical means.

The mill was visited and the manager interviewed. He stated that the manufacturers began making hosiery from the new synthetic fiber about one year ago and had sold many thousand dozen without receiving any complaints until April 1940. In April 1940 they began using a new finish and stated that they had sold about 1,000 dozen stockings finished with this product before they began to receive reports of dermatitis occurring from their hose. They then wrote to the Public Health

Service, and on receiving the reply stating that the finish should be suspected they stopped using it and succeeded in recalling from the retail stores about 300 dozen stockings. All the proved cases of dermatitis in Indiana were traced to stockings made in this one mill and

Fig. 2.—Patch test to finish taken off pajamas and applied to surgical aseptic gauze.

processed with the new finish. This finish proved to be the same as that which caused the dermatitis when used on cotton fabrics in Canada and elsewhere.

HOSIERY MANUFACTURING PROCESS

The cones of thread as brought from the new synthetic fiber factory are placed in knitting machines and knit into stocking legs. The thread as it comes off the cone passes through a lubricating emulsion before it is knit. The knit legs are taken to other machines, which knit and fasten the feet onto them. The thread in these machines passes through a similar emulsion to that used on the leg machines. The heels and toes are then looped together to close the foot. This is done on separate machines. The whole stocking is then seamed at the bottom of the foot and the back of the leg to form the closed stocking.

The stocking is then mounted on flat metal forms and placed in a chamber containing steam under pressure. This process, called "preboarding," softens the thermoplastic resin of which the thread is made and thus sets and shapes the hose. After the stockings come out of this steam chamber they are inspected for flaws by pulling and stretching over leg-shaped forms. They are then placed in cotton sacks, about four dozen to the sack, and taken to the dye house. The sacks are placed in metal drums and immersed and heated in about 50 gallons of a solution consisting of 2 per cent soap, 5 per cent wetting-out agent, 3 per cent trisodium phosphate (tetrasodium pyrophosphate may be used) and 10 per cent sulfonated castor oil containing dichlorethyl ether (the percentages given are on the weight of the stockings to be dyed). To this "boil-off" bath is also added the required amount of synthetic dyes to color the stockings. The dyes used are the same class as are used for acetate silk (acetamine and cellanthrene colors). The dyers state that the new synthetic fiber dyes better when the "boil-off" and the

dyeing is done in one operation, but as far as the dermatitis hazard to the wearer is concerned it would be preferable to make one operation of the "boil-off" and empty the drums of the "boil-off" liquor before the dyeing solution is put in. The spent "boil-off" liquor when discharged would then remove all the oils and sizing which are used on the thread in order to facilitate knitting. As it is, these oils and sizings in the dye bath are likely to remain on the thread with the dye and are potential skin irritants.

After the operation of scouring and dyeing, the drum is drained and the stockings are given three rinses of water, after which the drum is again emptied and the solution of the finish is poured into the drum and applied to the hose. The finish now used and which was used previous to April 1940 is essentially an emulsion of a compound of a methylmethacrylate resin.

After the finish is applied, the stockings are placed in a centrifugal and the water extracted. The damp hose from the centrifugal are placed on hot metal forms to give them final shape, a process known as "boarding."

No cases of occupational dermatitis occurred in this mill among any of the workers handling the hose up to the "boarding" process. However, while the finish which caused the dermatitis was being used on the hose, one girl working at the "boarding" operation where she came in contact with the hot, damp finished stockings contracted an occupational dermatitis of her hands and arms which promptly cleared up when she was transferred to another operation. After "boarding," the hose are inspected, paired and packed. Samples of hose before the "boil-off" and dyeing, samples after dyeing, and samples after the finishing were obtained for patch testing.

Inspections at four other hosiery mills showed no material differences in the manufacturing process except that the finish causing the dermatitis had never been used in these mills, and one of the mills "boiled-off" and dyed in separate operations. The officials of two of these mills stated that they had had no reports of dermatitis from their new synthetic fiber stockings despite the fact that during the past year they had sold

Fig. 3.—Patch test to finish C diluted with 10 parts of water and applied to aseptic white gauze. Note flare-up of eruption.

more than 50,000 dozen pairs. In the third mill it was stated that two cases of dermatitis were reported as occurring from their hose during the year that they had been making the new synthetic fiber hose. One of these patients was seen by us and stated that she had itching but no eruption after wearing the hose. Patch tests performed on this patient by us showed a slight

reaction to the hose in that stage of manufacture after it came out of the "boil-off" and dyeing operation, but there was no reaction to a patch of new hose finished with the old finish (case 5, table 2). This seems to confirm the fact that by "boiling-off" and dyeing in one operation some of the oils and sizings are left on the hose and may cause dermatitis. In the fourth mill, where the suspected finish was not used, we were told that they had heard of only one case of dermatitis suspected to have been caused by their new synthetic fiber hose, although in the past year they had sold more than 20,000 dozen.

In an effort to discover the actual irritant that caused the dermatitis from wearing the new synthetic fiber hose, patch tests were performed on nine patients who were said to have had dermatitis from wearing them and who volunteered for these tests. Four of these had been definitely proved by one of the authors to have had dermatitis from wearing hose finished with the suspected finish. The proof consisted in positive patch tests to the hose which they wore and from which they claimed to have contracted dermatitis. The fifth was the one cited who reacted to the hose after the "boil-off" and dyeing operation but did not react to new hose finished with the old formula. The four other patients were women working in the mill where the stockings causing the dermatitis were made and who stated that they had developed dermatitis from wearing them but who were treated by the nurse in the mill and not seen by a physician. All nine patients had recovered by the time these patches were applied.

The patches applied for forty-eight hours are as follows:

1. New synthetic thread, unoiled and unsized as obtained from the factory making it.

2. New synthetic thread on the cone, oiled and sized as sold by the factory making it.

3. New synthetic fiber stockings after "preboarding."

4. New synthetic fiber stockings after "boil-off and dye."

5. New synthetic fiber stockings after being finished with the old finish and "boarded."

6. A piece of scoured and dyed new synthetic fiber stockings dipped in a solution consisting of 1 part of finish A and 9 parts of water.

7. Scoured and dyed new synthetic fiber hose dipped in a solution of 1 part of finish B and 9 parts of water.

8. Scoured and dyed new synthetic fiber hose dipped in a solution of 1 part of finish C and 9 parts of water.

Finish A consisted of an emulsion of paraffin in a wetting-out agent. This finish has been used on natural silk hose for many years. Finish B consisted of an emulsion of a compounded methylmethacrylate resin. It is the old finish which was used on the hose before dermatitis occurred and is again being used on the new synthetic fiber. Finish C is the finish which was proved to have caused dermatitis when it was used on cotton and which was the finish used on the batch of hose causing the dermatitis. It is an emulsion of an acid ester gum. Table 2 shows the results of the patch tests.

It will be noted that all of the four subjects who were proved by patch tests to have had dermatitis from the hose reacted markedly to patch 8, the hose finished with finish C. One of the proved cases gave a lesser reaction to finish B than to finish C and another gave lesser reactions to the hose in stages 3 and 4 of its manufacture and to finish A.

One of the two among the five unproved subjects who reacted to finish C also reacted to the other finishes but to a lesser degree and she also reacted to patches

1 and 2. The other three subjects gave no reactions and hence their dermatitis was probably not caused by the hose.

The tests show that while sensitization may occur in some individuals to the new synthetic fiber itself, to the sizing and the oils on it (we know from other investigations that eugenol, the essential oil used in the emulsion, is a sensitizer), to the emulsion used in the knitting, to the mixture in the "boil-off" and dyeing solutions (this contains all the oils and sizings previously used on the thread as well as strong alkalis and dyes) and to the other finishes, yet all of the six patients who reacted to any of the finishes reacted most strongly to finish C. This is the finish that was used on the batch of hosiery to which the outbreak of dermatitis was traced and is the same finish which was proved to have caused the outbreak of dermatitis from cotton fabrics. Three of the six who reacted to the finish reacted only to finish C, and the other three reacted most strongly to

finish C. All the six who reacted to finish C reacted strongly to adhesive plaster, which also contains abietic acid, which we believe to be the irritant ingredient in the ester gum contained in finish C actually causing the dermatitis. Hence it can be said that, while dermatitis may be caused in sensitive persons by any of the finishes and even by many natural fabrics like wool and silk, yet the major cause of the outbreak of dermatitis from hose and other wearing apparel described in this paper was the use of finish C. Those persons who developed dermatitis a few days after wearing the stockings were probably already sensitive to the resin in the finish (perhaps they acquired this sensitivity by previous contact with adhesive plaster), while those who developed dermatitis ten days or more after wearing the hose were sensitized by the resin in the finish.

As a result of these investigations this finish is no longer recommended by its manufacturers for use on wearing apparel.

Finishes are placed on fabrics in order to give them a better appearance, a better feel and better wearing properties, and to prevent runs and make them noncreasing and sometimes to hold the crease. Their stay

on the fabric is more or less temporary, for while part of the finish may remain after many washings the first laundering usually removes a large proportion of it. The fact that fabric finishes are often the causes of dermatitis when dyes are blamed was first proved by Schwartz.²

The sulfonated oils which were previously used as finishes have largely been supplanted by finishes made of various new synthetic resins. The urea formaldehyde resins, the alkyd resins, the methylmethacrylate resins and ester gums are used in modern finishes. Some of these resins are also used as vehicles for new types of fabric dyes. Recently fabrics have appeared on the market which are coated with resins containing antiseptics. These resins are often mixed with various plasticizers and stabilizers in order to give them the required properties necessary for use in wearing apparel. Resins are also used as plastic materials from which are manufactured such articles as belts, suspenders, wrist watch straps and garters.

Not only are the resins themselves capable of producing sensitization, but many of the plasticizers, stabilizers and antiseptics used in them are primary skin irritants as well as sensitizers.

Outbreaks of dermatitis caused by dyes, leather, rubber, plastics and fabrics in wearing apparel have often previously been reported. Manufacturers are placing materials containing new substances of unknown toxicologic properties on the market for wear before testing their action on the human skin. As a result there have been new outbreaks of dermatitis such as are described in this paper. Such outbreaks will continue to occur as long as this practice continues.

Therefore it is suggested that, before any new chemical or combination of chemicals is to be sold to the consumer for the purpose of wearing apparel or as a fabric finish or dye, the manufacturer should have toxicologic laboratories investigate the skin irritating and sensitizing properties of such new chemicals and make them known to their customers.

There should be standard tests for determining these facts. The following test is proposed: All new chemicals that may be used in wearing apparel should first be tested on susceptible animals (rabbits) to determine whether these chemicals are primary skin irritants. The test should consist in the application of the chemical to the shaved skin of a rabbit under a patch for twenty-four hours. Any irritation at the point of contact of the chemical with the skin is proof that the chemical is a primary skin irritant. If it is found that the chemical is not a primary skin irritant, it should be tested on animals for its sensitizing properties by applying it as a patch test for forty-eight hours ten days after the first series of patch tests. The manufacturer of the chemicals should make known to the customer the results of these tests.

Wearing apparel containing chemicals which have not been used before on fabrics should be first tested on ten or twelve persons to determine whether they are primary skin irritants or sensitizers. If it is found that the wearing apparel does not affect these people, a larger number (about 200) should be tested in the following manner: A piece of the new fabric should be applied in the form of a patch test for five days. As a control they should be patched at the same time with a fabric that has long previously been used for the pur-

pose for which this new fabric is intended and has not caused an unusual amount of dermatitis. The new fabric should not cause any more reaction than does the old. Ten days after the removal of the first patches a second series of patches should be applied to the same individuals and allowed to remain on for two days. This should give an idea of the percentage of people who can be sensitized by the new fabric as against the percentage that can be sensitized by the old.

Five days is suggested as the length of time for the application of the first patch tests to this large group of people, because any ordinary fabric that will not irritate the skin can safely be permitted to remain on the skin for that period and because the period of incubation for sensitization is usually six or more days. Hence, sensitization reactions should not result during the period that the first patch test is allowed to remain on the skin. Ten days is allowed after the removal of the first series of patch tests before the second series is applied in order to permit sensitization to develop.

If such a series of experiments show that a greater percentage are sensitized by the new fabric than by the old, then it is more hazardous and should if possible be modified in order to make it less so. Or if this is not possible it should be discarded as unsafe.

In addition to these precautions it should be required that dyes, finishes, plasticizers, stabilizers, antioxidants and accelerators used on wearing apparel should be of such a nature or so incorporated into materials that they will not come off or out of the material under the action of a normal amount of perspiration.

To assist manufacturers and better to protect the general public, it is suggested that the conclusions of such toxicologic laboratories should be submitted to the state department of health and labor of those states having industrial hygiene units, which in turn could call on the Office of Dermatoses Investigations whenever needed.

We believe that if these suggestions, or similar ones, were carried out, not only would the public be safeguarded from outbreaks of dermatitis such as here described, but the retailers would be saved the annual loss of large sums of money.

SUMMARY

Seemingly separate outbreaks of dermatitis in the United States and Canada caused by wearing apparel made of different fabrics were investigated and found to be due to a common cause.

A certain finish used on these fabrics was proved to be the cause. This finish is essentially an emulsion of an acid ester gum.

The acid ester gum was proved to be the chief irritant.

As a result of these investigations the finish was withdrawn by its manufacturers for use on wearing apparel.

RECOMMENDATIONS

Manufacturers of chemicals should have toxicologic and dermatologic tests performed on their chemicals and acquaint the buyers with the results.

Manufacturers of wearing apparel containing new chemicals should have studies made of the effect of these chemicals on the skin before placing them on sale to the public.

A method has been devised for performing such skin studies.

It is recommended that the buyer launder all new underwear, stockings and other garments that touch the skin, before wearing.

HYPERTENSION AND CHRONIC
ATROPHIC PYELONEPHRITIS

RESULTS OF NEPHRECTOMY

NELSON W. BARKER, M.D.

AND

WALTMAN WALTERS, M.D.

ROCHESTER, MINN.

The experiments of Goldblatt¹ and others² who have shown that hypertension may be produced in dogs by partial constriction of the renal arteries by means of metal clamps have stimulated a more careful search for primary localized renal disease, particularly chronic pyelonephritis, in human beings with so-called essential hypertension. Although there is no evidence of chronic pyelonephritis in the majority of cases of essential hypertension, several investigators (Longcope,³ Butler⁴ and Weiss and Parker⁵) have felt that the association of these conditions was frequent enough to be more than incidental. Butler has reported a case in which hypertension was associated with unilateral chronic pyelonephritis in a child aged 7 years. Surgical removal of the affected kidney was followed by return of blood pressure to normal; the pressure had remained normal for twenty months at the time of Butler's report. Barney and Suby⁶ have reported a similar result of nephrec-

tomy was performed for chronic pyelonephritis or hydronephrosis associated with hypertension. The hypertension disappeared in all three cases; but in one case, in which there was disease in the remaining kidney, the hypertension recurred within a year. In a second case there was recurrence after the blood pressure had been normal for ten years. It also has been felt that localized vascular lesions of the kidney might be responsible for hypertension in rare instances. Leadbetter and Burkland⁸ have reported relief of hypertension in a Negro boy following removal of an ectopic kidney in which the main artery was partially occluded. Boyd and Lewis⁹ reported a similar effect after removal of a kidney containing multiple infarcts.

REPORT OF CASES

We report five cases of hypertension associated with unilateral chronic atrophic pyelonephritis in which nephrectomy resulted in return of the blood pressure to normal levels.

CASE 1 (A preliminary report has been published elsewhere¹⁰).—A man aged 42 came to the Mayo Clinic in November 1937. A large stone had been removed from his right ureter in 1933 elsewhere. At that time the kidney appeared to be of normal size in the urogram; in 1935 the kidney had been found to be moderately contracted; in 1937 it was markedly contracted. His blood pressure had been normal at numerous examinations prior to March 1936. In August 1937 his systolic

Fig. 1.—Hourly blood pressures taken with patient at rest, reactions to cold pressor test and follow-up studies in case 1 before and after nephrectomy.

tomy for unilateral chronic pyelonephritis in a case of hypertension in which the patient was 10 years of age. Crabtree⁷ has reported three cases in which nephrec-

tomized the blood pressure had been 200 mm. of mercury and the diastolic pressure 140. He stated that there was no known hypertension in his family.

In November 1937 the first blood pressure was 232 mm. systolic and 135 diastolic. Examination disclosed slight sclerosis and moderate narrowing of the retinal arteries and scattered small retinal hemorrhages. Retinal exudates and edema of the optic disks were not present. Chemical examination of the urine on several occasions did not disclose albumin or sugar, but microscopic examination showed hematuria grade 1 and pyuria grade 3. A roentgenogram of the thorax revealed that the transverse diameter of the heart was 11.5 cm. The electrocardiogram showed only left ventricular preponderance. The concentration of blood urea was 34 mg. per hundred cubic centimeters and that of serum sulfates 3.9 mg. per hundred

cubic centimeters. Excretory urography disclosed marked contraction and distortion of the right kidney and slight dilatation of its pelvis and calices but showed only moderate reduction of renal function (fig. 2). The left kidney appeared entirely normal. Ureteral catheterization revealed an impassable stricture in the upper part of the right ureter. Excretion of indigo

Fig. 2.—Excretory urogram in case 1, showing marked contraction of the right kidney.

carmin was grade 3 plus in the urine from the left kidney and grade 2 in the urine from the right kidney. A few leukocytes were found in the urine from the right kidney but none were found in that from the left kidney. Organisms were not obtained on culture of urine obtained by ureteral catheterization from either kidney, but *Escherichia coli*, micrococci and *Pseudomonas* were obtained from vesical urine.

The right kidney was removed Nov. 19, 1937; it was approximately a third of the normal size and weighed 48 Gm. (fig. 3). Its surface was nodular and contained numerous projections from a few millimeters to 1 cm. in diameter. The histologic picture was typical of chronic atrophic pyelonephritis. Slight dilatation of the pelvis and some thickening of the pelvic mucosa were present but there was no evidence of acute inflammatory reaction. Stones were not found. The cortex of the kidney consisted of alternate portions of normal renal tissue interspersed with portions of equal size in which the parenchyma had been destroyed almost completely and replaced by fibrous tissue containing numerous lymphocytes and fibroblasts. The arcuate and interlobular arteries in these portions had markedly thickened walls mostly as the result of intimal proliferation. Arteries with a lumen-to-wall ratio greater than 1:1 were not seen. In many of the arteries this ratio was reduced to 1:5 to 1:6 and the lumen of some of the arteries was completely obliterated (fig. 4).

The hourly readings of the blood pressure taken with the patient at rest and the responses of blood pressure to the cold pressor test before operation and eighteen days after operation are shown in figure 1. After the postoperative convalescence, roentgenograms of the heart and the electrocardiograms were unchanged. Examination of the ocular fundi disclosed only slight sclerosis and narrowing of the retinal arteries. The hemorrhages had disappeared.

Numerous determinations of the blood pressure were made during the next eighteen months. The average reading was 130 systolic, 90 diastolic and the maximal was 140 systolic, 100 diastolic, during this period. At the end of eighteen months the cold pressor test raised the blood pressure to only 150 systolic, 100 diastolic. At the end of two years the blood pressure was 130 systolic, 90 diastolic.

CASE 2.—A man aged 46 came to the clinic in February 1939; his chief complaint was headache of two months' duration. The headache had occurred chiefly when he awoke each morning

and at times had been very severe and had lasted all day. Acetylsalicylic acid had not relieved the headache and he had found it necessary to take codeine many times for relief. One week before the headaches had begun he had had painless hematuria. Cystoscopic examination at that time had revealed a stone in the right kidney. He had been a patient at the clinic in 1931 because of gastrojejunal ulcer, for which a gastric resection had been done. At that time his blood pressure had been 116 systolic, 90 diastolic and 120 systolic, 90 diastolic on two occasions. He stated that it had been taken several times at the recent cystoscopic examination and had been pronounced normal. He did not know of any instances of hypertension in his family.

Examination revealed that his blood pressure was 178 systolic, 118 diastolic. Examination of the retinal arteries showed narrowing grade 1 plus and sclerosis grade 1. There was no retinitis. No enlargement of the heart was noted on physical or roentgenographic examination. The maximal specific gravity of the urine was 1.025. Albuminuria and glycosuria were not present. A few erythrocytes and a moderate number of leukocytes were found in the urine. The concentration of urea was 20 mg. per hundred cubic centimeters of blood. Excretory urography showed the left kidney to be normal and to have normal function. The right kidney excreted the medium only slightly at the end of twenty minutes. It was small and atrophic and its pelvis was filled with a large branched stone (fig. 5).

The right kidney was removed Feb. 21, 1939; it weighed only 70 Gm. and contained a stag-horn calculus which filled its pelvis. It was estimated that 50 per cent of the renal parenchyma had been destroyed by irregular pyelonephritic scarring. There was marked thickening of the walls of all arteries and arterioles in the scarred regions. The lumen-to-wall ratio varied from 1:2 and 1:5 (fig. 6).

The blood pressure readings determined hourly before and after operation and the response of the blood pressure to the cold test are shown in figure 7. When the patient was seen in

Fig. 3.—Appearance of right kidney in case 1, showing marked irregularity and scarring of the cortex and increase in the peripelvic fat.

the office six months after the operation his blood pressure was 120 systolic, 85 diastolic. He said that he had not had any headache since the operation.

CASE 3.—A married woman aged 34, who never had been pregnant, came to the clinic complaining of left renal colic which had occurred once or twice a year for ten years. To her knowledge she had not passed stones or had hematuria, chills or fever with the attacks. For a year and a half before

she came to the clinic she had had dull frontal headache about once a month. Her blood pressure had been found to be normal at examinations ten and four years previously. She did not know of any members of her family who had had hypertension.

Examination revealed moderate spasm and tortuosity of the retinal arteries with slight sclerosis. There was no evidence of retinitis or demonstrable enlargement of the heart. Pelvic

Fig. 4.—Section of kidney in case 1 showing marked destruction of the renal parenchyma with replacement by chronic inflammatory tissue, and marked thickening of the walls of the arteries and reduction in the size of their lumens; slightly reduced from a photomicrograph with a magnification of 50 diameters.

examination disclosed a movable firm tumor which extended 10 cm. above the symphysis pubis. This was believed to be a fibromyoma of the uterus.

Examination of the urine showed albuminuria grade 2 on a basis of 1 to 4; otherwise, the urine was normal. A roentgenogram of the thorax and an electrocardiogram did not reveal anything abnormal. The concentration of blood urea was 30 mg. per hundred cubic centimeters. Intravenous urography revealed a functionless left kidney and slight pyelectasis and caliectasis of the right kidney, which was functioning normally and was normal in size. Retrograde pyelography revealed a markedly contracted left kidney with a medially displaced pelvis.

The blood pressure on admission was 200 systolic, 126 diastolic. When taken hourly during a period of rest in the hospital it varied between 195 systolic, 125 diastolic and 160 systolic, 105 diastolic. The maximal response of the blood pressure to the cold pressor test was 190 systolic, 150 diastolic and the minimal blood pressure after anesthesia with pentothal sodium administered intravenously was 130 systolic, 95 diastolic.

The left kidney was removed. Twelve days later the blood pressure varied between 120 systolic, 85 diastolic, and 110 systolic, 75 diastolic, and on dismissal eighteen days after operation it was 130 systolic, 90 diastolic.

When the patient was reexamined one year later she had no complaints. Her blood pressure varied between 130 systolic, 100 diastolic and 125 systolic, 85 diastolic, and urinalysis did not reveal any abnormality. The concentration of blood urea was 38 mg. per hundred cubic centimeters and there was no spasm of the retinal arteries.

The left kidney weighed 18 Gm. (fig. 8). There was very little normal renal parenchyma remaining and for the most part the tissue consisted of extensive scars with remnants of destroyed tubules and hyalinized glomeruli. The arteries and arterioles in the scarred regions showed marked thickening of the wall and reduction of the lumen as the result of intimal proliferation in most instances.

CASE 4.—A housewife aged 52 came to the clinic because of persistent dull pain in the right side of the upper part of the abdomen. The pain had been associated with lumbar backache and had been present for two months. The patient had not menstruated for ten years. She had had severe periodic headaches for more than thirty years. Two months prior to coming to the clinic she had been told that her blood pressure was

elevated. It had not been taken previously to this time. She stated that one sister had high blood pressure.

Examination revealed moderate narrowing and slight but definite sclerosis of the retinal arteries without retinitis. Examination of a specimen of urine which was obtained by catheterization revealed a trace of albumin and numerous pus corpuscles. The concentration of blood urea was 24 mg. per hundred cubic centimeters. Roentgenologic examination of the thorax revealed that the transverse diameter of the heart was 11.5 cm. Intravenous urography revealed an apparently normal left kidney and a functionless right kidney. Cystoscopic examination revealed pus coming from the right ureter and an impassable obstruction 2 to 3 cm. from the ureterovesical juncture. Culture of the vesical urine produced *Escherichia coli*. When the patient was first examined at the clinic her blood pressure was 186 systolic, 110 diastolic.

The right kidney was removed. Following the operation the blood pressure rapidly fell to 125 systolic, 70 diastolic. When the patient returned for a checkup ten months later her blood pressure was 125 systolic, 85 diastolic. At a second checkup thirteen months after operation her blood pressure was 128 systolic, 90 diastolic. The kidney weighed 52 Gm. Approximately 90 per cent of the renal parenchyma had been destroyed and replaced by chronic inflammatory fibrous tissue. In the involved regions there was marked thickening of the arteriolar walls, which was chiefly the result of proliferation of the intima.

The following case is presented only as a preliminary report, as insufficient time has elapsed since nephrectomy was done to permit of proper evaluation. However, since malignant hypertension with severe retinitis and edema of the optic disks is uncommon among children and since a return of blood pressure to normal with involution of the retinitis followed nephrectomy, a preliminary report of this case seems justified.

CASE 5.—A girl aged 7 years was brought to the clinic by her mother because of headaches. She had had occasional headaches since the age of 2 years, but these had increased

Fig. 5.—Excretory urogram in case 2, showing marked contraction of the right kidney.

markedly in frequency and severity during the past nine months and particularly during the past three months. Nine months previously she had had measles of severe degree. At that time albumin had been found in the urine and her systolic blood pressure had been found to be 180 mm. For the past five weeks her mother had noticed that the right eye turned inward. Examination of the eyes showed definite weakness of the right external rectus muscle, marked spasm of the retinal

arteries, extensive retinal exudates and hemorrhages, and edema of the optic disks measuring from 5 to 6 diopters in both eyes. Her heart was definitely enlarged. Urinalysis showed albuminuria grade 2 on the basis of 1 to 4 but the urine was otherwise normal. Roentgenologic examination of the thorax showed apparent dilatation and torsion of the arch of the aorta with prominence of the aortic knob along the left border of the mediastinum. Normal pulsations were present in the arteries of the lower extremities. Her blood pressure on admission was 210 systolic, 160 diastolic. During a period of rest in the hospital the blood pressure varied between 210 systolic, 166 diastolic, and 170 systolic, 140 diastolic. The mean pressure was 207 systolic, 147 diastolic. The cold pressor test increased the blood pressure to 234 systolic, 176 diastolic. No history could be obtained which suggested any localized renal disease but an excretory urogram showed no evidence of secretion from the left kidney. A retrograde pyelogram showed that the left kidney was very small and had abbreviated clubbed calices. The right kidney appeared to be normal in the urograms and its function was normal. The left kidney was removed. The kidney was very small, weighing only 9 Gm. The pelvis was somewhat dilated and there was an anomalous artery crossing the ureteropelvic juncture. Microscopic examination showed marked destruction of the tubules throughout most of the kidney substance and hyalinization of almost all the glomeruli. There

Fig. 6.—Section of kidney in case 2, showing marked destruction of the renal parenchyma with replacement by chronic inflammatory tissue and marked thickening of the walls of the arteries and reduction in the size of their lumens; slightly reduced from a photomicrograph with a magnification of 40 diameters.

was extreme thickening of the walls of the blood vessels, the lumens of which were practically obliterated in many instances. The patient's postoperative convalescence was uneventful. Her blood pressure gradually fell until on the sixth postoperative day it was 130 systolic, 104 diastolic. From the eleventh to the twentieth postoperative day it varied between 100 systolic, 84 diastolic, and 120 systolic, 90 diastolic. The cold pressor test on the twentieth postoperative day showed that the maximal blood pressure was 140 systolic, 104 diastolic. Examination of the retinas on this day also showed a few absorbing exudates but no hemorrhages. There was no arterial spasm and there was a marked reduction in the edema of the optic disks to 2 diopters. The weakness of the right external rectus muscle had entirely disappeared.

At a checkup three months after nephrectomy her blood pressure varied between 102 systolic, 70 diastolic and 122 systolic, 84 diastolic and did not rise at all during the cold pressor test. There was no edema of the optic disks but a few residual exudates were present in the retinas. Follow-up studies of this patient will be reported at a later date.

COMMENT

It is our opinion that in these five cases the return of the blood pressure to normal levels and its persistence at normal levels following nephrectomy is ample evidence that the diseased kidney was the chief factor in

the production of the hypertension. In the first three cases it can be said with reasonable certainty that the renal disease was advanced when the hypertension first developed. In the fourth and fifth cases it is not known definitely when either the hypertension or the renal disease began.

Fig. 7.—Hourly blood pressure taken at rest, reactions to cold pressor test and follow-up studies in case 2 before and after nephrectomy.

With regard to the hypertension, certain common characteristics were noted in all of the cases. None of the patients had evidence of advanced organic arterial damage, and in those cases (cases 1, 2 and 3) in which there were some data regarding the duration of the hypertension it had not existed for a long period. All

Fig. 8.—Kidney in case 3, showing marked atrophy of the parenchyma, pyelectasis and caliectasis.

the patients had relatively high diastolic blood pressures compared with the systolic.

With regard to the renal disease, all had contracted atrophic kidneys weighing less than 75 Gm. (that is, less than half the normal weight), all had extensive chronic pyelonephritis with destruction of renal parenchyma and all had marked thickening of the arterial walls in the scarred regions.

Similar observations were made in one of the cases reported by Butler. In their study of pyelonephritis and hypertension, Weiss and Parker stated that a mild degree of hyperplastic arteriolar sclerosis in both kidneys is usually associated with normal blood pressure, a severe degree of hyperplastic arteriolar sclerosis in unilateral pyelonephritis may or may not be associated with hypertension, and a severe degree of hyperplastic arteriolar sclerosis in both kidneys is practically always associated with severe hypertension.

In the five cases which we have reported, the cause of the marked thickening of the renal arteries has not been determined. The arteries in the regions in which the renal parenchyma was well preserved appeared to be normal. The thickening was not confined to the

nation disclosed that twenty-six (45.6 per cent) of the patients had a blood pressure greater than 145 systolic, 90 diastolic.

We next studied a consecutive series of twenty-four cases in which pathologic examination of a kidney that was removed at operation revealed the presence of chronic atrophic pyelonephritis and a kidney that weighed less than 75 Gm.

The blood pressures in these cases were reviewed and careful pathologic studies of the kidneys were made. A summary of the data is given in the accompanying table. The first five cases are those which we have reported in detail.

It will be noted that the blood pressures in excess of 145 systolic, 90 diastolic, were found in fifteen, or 62.5 per cent, of the cases and that the first eleven (45.8 per cent) can be said to have had a definite hypertension. We have no follow-up data at the present time on the effect of nephrectomy on the blood pressure in cases 6, 7, 8 and 9. In cases 10 and 11 the blood pressures a year after operation were 130 systolic, 110 diastolic, and 145 systolic, 80 diastolic, respectively, but in each case an extensive sympathectomy was done at the time of nephrectomy, so that we cannot say that the lowering of the blood pressure was the result of nephrectomy alone.

It is also noteworthy that in all of the cases with definite hypertension there was marked thickening of the arteries in the scarred regions of the kidneys but that only moderate thickening of these arteries was found in four of the nine cases in which the blood pressure was normal. In the other five cases in which the blood pressure was normal there was marked thickening of the arteries, but in two of the cases there was also extensive suppuration of the kidneys (pyonephrosis) and the other three patients were relatively young individuals as compared with the patients who had definite hypertension.

It must be emphasized again that localized renal lesions are not commonly found in cases of so-called essential hypertension. Thus, in 100 cases of hypertension in which blood pressure studies were conducted in the hospital and in which urograms had been made, chronic atrophic pyelonephritis was found in only four. Further urographic studies in a large series of cases of hypertension and studies of the effect of nephrectomy for other types of renal lesion as well as chronic atrophic pyelonephritis are advisable.

SUMMARY

This paper is based on five cases of unilateral chronic atrophic pyelonephritis associated with hypertension. In each case the blood pressure returned to normal after nephrectomy and it has remained within normal limits for a number of months in four cases. Insufficient time has elapsed to evaluate thoroughly the fifth case. In each case pathologic studies revealed extensive atrophy and scarring of the diseased kidney with marked thickening of the walls of arteries in the scarred portions.

In twenty-six, or 45.6 per cent, of a series of fifty-seven cases in which a diagnosis of chronic atrophic pyelonephritis was made urographically there was an elevation of blood pressure. In a series of twenty-four cases in which chronic atrophic pyelonephritis was diagnosed pathologically after nephrectomy fifteen, or 62.5 per cent, showed an elevated blood pressure and eleven, or 45.8 per cent, definite hypertension.

There is evidence to believe that the hypertension is the result of obstruction of the renal arteries.

Blood Pressure When Patients Were First Observed at the Clinic and Pathologic Changes in Cases of Unilateral Chronic Atrophic Pyelonephritis in Which Nephrectomy Was Performed

Case	Age, Yrs.; Sex	Blood Pressure, Mm. of Mercury	Weight of Kidney, Gm.	Renal Lesions and Percentage of Renal Parenchyma Involved by Scar Tissue	Thickening of Arterial Walls, Grade*

* Basis of 1 to 4.

arterioles but was also seen in the interlobular and arcuate arteries. It was partly due to increased thickening of the muscular coat and partly to extensive hyperplasia of the intima. There are three possibilities: (1) The arteries may be thickened as the result of arteritis which is part of the chronic inflammatory reaction in the renal parenchyma, (2) they may be thickened as the result of contraction by the scar tissue, and (3) they may be thickened because of more distal obstruction to the capillaries associated with the destruction of the renal parenchyma. As the scarred regions containing the thickened arteries comprised a large portion of the renal tissue in each case, there can be no doubt that in each case there was considerable obstruction to the renal arterial blood flow.

Because of the similarity of the renal lesions in the five cases it was thought advisable to study the incidence of hypertension in a larger series of cases of chronic atrophic pyelonephritis. A review of a consecutive series of fifty-seven cases in which a diagnosis of chronic atrophic pyelonephritis was made by urographic exami-

TREATMENT OF PNEUMOCOCCIC MENINGITIS

Although the newer chemotherapeutic agents have not changed the outlook in pneumococcic meningitis as strikingly as in streptococcic meningitis, their use, together with specific serum, has made the prognosis much more hopeful in this highly fatal disease. In the past three years there have been several reports of small groups of cases or single cases in which recovery appears to have resulted from these agents, used alone or in combination.¹

Prior to July 1938 only one of us had observed a recovery in pneumococcic meningitis. Between 1912 and 1937 there had been two recoveries at Cook County Contagious Hospital. Perusal of the medical literature confirmed the impression that prior to 1937 this disease had been almost invariably fatal.²

From July 1, 1938, to Feb. 1, 1940, we treated twenty-two patients, seven of whom recovered. Only the cases in which recovery occurred are described in

detail in this communication, but to determine the relative frequency a survey was made of all cases of pneumococcic meningitis at the Cook County Hospital from Jan. 1, 1937, to Feb. 1, 1940. To our surprise there were seventy-one cases during this period. Among all the cases of meningitis at the Cook County Hospital, only tubercle bacilli and meningococci were ahead of pneumococci numerically as etiologic agents (table 1).

Surprisingly, during the twenty month period in which our twenty-two cases occurred, there were altogether thirty-eight cases of pneumococcic meningitis in the hospital, while only thirteen cases of meningococcic meningitis were admitted. Obviously the old teaching that all patients with purulent meningitis should be treated as having meningococcic meningitis until proved otherwise is entirely obsolete. Now it is best to start sulfapyridine or its sodium salt when in doubt, unless there are unusual contraindications. Every effort must be made to establish an etiologic diagnosis quickly so that other proper specific measures may be used. Six times among the thirty-three patients treated prior to our series antimeningococcus serum was given to patients with pneumococcic meningitis under a mistaken diagnosis. In our own series of fatal cases, one patient had been treated in this way prior to the time he came to us, and we mistakenly treated the patient for meningococcic meningitis for two days before the etiologic agent was determined.

Table 2, giving the results of a survey of all cases of pneumococcic meningitis in a three year period at the Cook County Hospital, shows the wide variety of pneumococcus types responsible for meningitis. In the cases reviewed (table 3), it is seen that pneumococcic meningitis, unassociated with other lesions, i. e. "primary," is relatively uncommon. Pneumonia, both confluent lobular and lobar, was the lesion most frequently associated with pneumococcic meningitis. Usually this preceded the meningitis but was in some instances undoubtedly a sequel. Otitis media was the next most common associated pathologic change and when present was usually the atrium of infection, although in four cases both otitis media and pneumonia were present. Four cases of pneumococcic meningitis occurred in persons with old healed skull fractures. It is doubtful whether there was any etiologic relationship in these cases, but in the three cases associated with recent skull fractures the atrium of infection may have been the torn dura.

We have been impressed with the studies of Osgood,³ Branham and Rosenthal,⁴ Gross and his associates,⁵ and others in which more and more evidence has been adduced that the therapeutic efficacy of specific antibody, as well as of sulfanilamide or of sulfapyridine, was enhanced by the use of the two simultaneously. In their studies this action was beyond that which would be expected from the simple additive effect of the two. Hence our plan was to use both sulfapyridine and specific antiserum if the type of pneumococcus could be obtained quickly and serum could be obtained.

The protocols reveal that sulfanilamide was used in our earlier cases, then sulfapyridine and later the sodium salt of sulfapyridine. The Lederle Laboratories

From the Cook County Contagious Hospital.

furnished us with the serum, and for eight patients in our series sulfapyridine was given to us by Merck & Co., Inc.

Although frequent determinations of the blood level of sulfanilamide and of sulfapyridine were not made in our earlier cases, the value of this check soon

became apparent. As pointed out by other workers, the spinal fluid concentration of these drugs seldom exceeds more than one half to two thirds the blood concentration in persons under treatment. Hence a blood level of from 15 to 20 mg. per hundred cubic centimeters is desirable. In practically every case there was marked cyanosis after sulfanilamide or sulfapyridine was started, but this was not considered an indication for stopping the drugs. In some of the sulfanilamide-treated cases secondary anemia supervened but was treated by blood transfusion rather than by withdrawal of the drug. No noticeable effect on the blood was observed with the use of sulfapyridine. In our small series of sulfapyridine-treated cases hematuria did not occur. There were no instances of anaphylactic shock. In a few instances the sharp thermal reaction so often produced by rabbit serum occurred. It always responded promptly to intravenous administration of calcium, and in no case was it necessary to discontinue intravenous serum.

PROTOCOLS OF CASES IN WHICH RECOVERY OCCURRED

CASE 1.—A Negro youth aged 15 had the usual signs of meningeal irritation when admitted on the eighth day of his illness but he was still conscious. There was slight injection of the right ear drum and he had a moderately inflamed throat. Type I pneumococci were found in cultures of the blood and spinal fluid but not in direct smears—a favorable prognostic sign. Recovery occurred after vigorous dosage with sulfanilamide and specific antiserum.

CASE 2.—A Negro girl aged 15 years was admitted on the third day after the onset of headache and pain in the left ear. The drum was incised at once and green pus escaped. Because

of a delay in typing the organism only sulfanilamide in large doses subcutaneously was given the first two days. After type XVII pneumococci were identified in the spinal fluid and blood, 80,000 units of specific rabbit serum was injected intravenously. Sulfanilamide was continued by mouth. Additional serum was given until a total of 340,000 units had been administered. This case illustrates the necessity of establishing drainage in all purulent lesions due to pneumococci, in addition to chemotherapy and serum therapy.

CASE 3.—A white girl aged 8 years was admitted because of stiff neck, fever and frequent convulsions of one day's duration. Examination revealed nothing noteworthy beyond the usual signs of meningeal irritation. In the spinal fluid the cell count was 7,900. No organisms were seen on direct smear, but the next day a growth of type VI pneumococci was obtained. Small doses of sulfanilamide were given on the second and fourth hospital days, but it was not given in consecutive doses each day until the sixth day of hospitalization. Type specific serum was started on the second hospital day and continued at frequent intervals through the eighteenth day. After fourteen days the temperature became normal and remained so until the twenty-eighth day, at which time there was some evidence of

fluid in the right side of the chest. X-ray examination revealed only a thickened pleura. A diagnostic thoracentesis was not done. The temperature returned to normal in four days.

In this case, as in others, the absence of large numbers of pneumococci in direct smears, together with a relatively high spinal fluid cell count, proved a favorable prognostic sign. The presence of an associated lesion in the chest, plus the inadequate dosage of sulfanilamide at the start of treatment, probably accounts for the large total dose of specific serum required for recovery in this case.

CASE 4.—A white man aged 76 was admitted in a semicomatose condition with signs of meningeal irritation. No associated pathologic changes were found in the lungs, ears and sinuses. In the spinal fluid, containing 1,500 cells per cubic millimeter, no organisms were seen, but cultures yielded large numbers of type XXXI pneumococci. Sulfanilamide 6.4 Gm. daily was given subcutaneously the first three days, after which time the patient was able to take it by mouth until three weeks after he became afebrile. Serum was continued to the sixth day. A blood transfusion was performed on the fourth day because of the patient's weakened condition.

This case shows that aged subjects may recover from pneumococcic meningitis if promptly and vigorously treated. The absence of associated focal pneumococcic lesions was, no doubt, important in recovery.

CASE 5.—Juanita W., aged 12 years, a Negress, was admitted to another hospital two days before admission to the Cook County Contagious Hospital because of generalized convulsions.

She was thought to have jacksonian epilepsy because of a known skull fracture in 1934, followed two years later by several convulsive seizures. Pneumococcic lesions beyond the meningitis were not found. Blood culture was negative. Sulfapyridine was started the day of admission and continued beyond her febrile period. Specific antipneumococcus serum (type

Chart 1.—Course in case 1.

XXIII) was started the third day of illness. The anemia, which necessitated blood transfusions, was thought to be due to sulfapyridine. The low level of sulfapyridine in the spinal fluid, as compared with that in the blood, is noteworthy.

Again, favorable prognosis in so-called primary meningitis as opposed to those complicated by other serious lesions is demonstrated.

CASE 6.—Marie F., aged 14 years, white, was admitted on the second day of a "primary" pneumococcic meningitis. Type XVIII organisms were identified directly in the spinal fluid and intensive therapy was begun at once. Sodium sulfapyridine was given the first two days to establish quickly an adequate blood level, after which oral doses of 2 Gm. every four hours were continued for four days to maintain it. When the dosage

Chart 2.—Course in case 2.

was dropped to 1 Gm. every four hours there was a recrudescence of the disease with a sharp rise in temperature. When the dose of sulfapyridine was increased, the temperature dropped again.

The microscopic agglutination test with type XVIII pneumococci was strongly positive on the eighteenth day of illness. The single spinal fluid level of sulfapyridine that was determined was found to be much lower than the blood level.

CASE 7.—Antonia R., a Mexican woman aged 42. was admitted on the seventh day of meningitis due to type X pneumococci. No associated pneumococcic lesions were present. Again the plan of intensive serum therapy at the start, combined with sodium sulfapyridine administered intravenously to attain a high blood level, quickly proved effective.

COMMENT

Only those who have observed cases of pneumococcic meningitis at first hand can appreciate how desperately ill these patients are before treatment is begun. Bacte-

remia is practically always present. In most cases there are also advanced pathologic changes (table 3) in other parts of the body. When vegetative endocarditis was present (table 4) we had no recoveries and found none in the reports of other workers. Extensive unresolved pneumonia of many days' duration was also an accompanying factor which presaged an unfavorable outcome. When the spinal fluid cell count was relatively low and the number of pneumococci in the centrifuged sediment quite high, the outlook was usually rather hopeless. On the other hand, a relatively high leukocyte count with few or no pneumococci

Chart 3.—Course in case 3.

on direct smear usually indicated a more favorable outcome. The best prognosis appears to be in those cases in which the disease is primary, i. e. unaccompanied by demonstrable pathologic changes elsewhere. Those cases secondary to otitis media, without pulmonary or cardiac involvement, have a reasonably good chance of recovery if drainage of the suppurative lesion is instituted quickly.

In reviewing our fatalities it was felt that only patient 1 (table 4) might have been saved by more prompt and vigorous treatment. Patient 14 became rational and afebrile after four days of treatment with sulfapyridine. The drug was continued, however. On the sixteenth day of illness the temperature again rose and focal signs pointing toward a lesion of the

Chart 4.—Course in case 4.

right hemisphere appeared. The patient died suddenly. At autopsy an abscess of the right frontal lobe with extensive purulent meningitis was found.

PRESENT PLAN OF TREATMENT

Since we are convinced that specific antibody should be given in cases of meningitis along with chemotherapy, our first concern after making the diagnosis of suppurative meningitis is to discover the etiologic agent. Gram stains of the spinal fluid are made at once and if organisms having the structure of pneumococci (or

meningococci, Bacillus influenzae, Friedländer's bacillus) are discovered, sulfapyridine is begun at once while pneumococcus typing by the Neufeld method is carried out.

In adults, unless there is some contraindication, such as known sensitivity to sulfapyridine, severe leukopenia or jaundice, the sodium salt of sulfapyridine in doses of from 4 to 6 Gm. in 5 per cent solution is given intra-

until the temperature has been normal for several days and until the spinal fluid and blood cultures are sterile. If possible, microscopic agglutination tests are done at intervals of from two to three days. Sulfapyridine should not be stopped before a four plus reaction has been obtained.⁶

When sulfapyridine cannot be swallowed by a comatose patient it may be administered, mixed with water or milk, through a small caliber stomach tube, introduced through an opening between the teeth forced by a wedge.

Specific antipneumococcal rabbit serum is given intravenously as soon as the organism is typed. If pneumococci are not present in large numbers in the spinal fluid, direct Neufeld typing may be impossible. If so, the test may have to be performed on the peritoneal exudate of a mouse, injected from four to six hours earlier with the spinal fluid, or on cultures of the spinal fluid. Large doses of serum—up to 600,000 units in one day in one case in our series—are given intravenously in the usual way after the usual precautions against serum reactions have been

Chart 5.—Course in case 5.

venously. This is repeated every twelve hours until a blood level preferably of from 10 to 20 mg. per hundred cubic centimeters is attained. Usually large doses up to 2 Gm. every four hours, day and night, by mouth are required to keep the level at this figure for the first few days. Later, slightly smaller doses of from 1 to 1.5 Gm. every four hours may suffice.

Chart 6.—Course in case 6.

For children the dosage is calculated on the basis of from 1 to 1½ grains per pound (0.065 to 0.1 Gm. to 450 Gm.) of body weight for each twenty-four hours, the dose being divided equally into six parts and administered every four hours, after an initial dose equaling one half the calculated day's dosage. That is, a child weighing 60 pounds (27 Kg.) would receive from 10 to 15 grains (0.65 to 1 Gm.) every four hours.

Usually the sodium salt needs to be administered for only two or three days. Sulfapyridine is continued

Chart 7.—Course in case 7.

taken. In adults the first day's dose is seldom less than 200,000 units.

Secondary anemia and occasionally leukopenia may result from the severity of the infection or from the use of sulfapyridine—more often the latter. When this occurs, our plan is to combat the anemia by frequently repeated transfusions of from 250 to 500 cc. of blood rather than by withdrawal of the drug, unless there are other important reasons why sulfapyridine should be stopped.

Surgical removal or drainage of any infected foci, particularly the sinuses and ears, is extremely important. The fluid intake and output should be carefully recorded, and if the output is adequate fluids up to 3,000 cc. daily are administered intravenously or by hypodermoclysis. In cyanotic patients, particularly those with associated pneumonia, oxygen is administered if possible.

SUMMARY AND CONCLUSIONS

1. In a series of twenty-two consecutive cases of pneumococcal meningitis treated by us with the combined use of sulfanilamide or sulfapyridine (and its

C., pneumococci 4 plus	XVIII	+	+	700 cc.	0	17 Gm.	632,000 units	Extensive purulent leptomeningitis; confluent lobular pneumonia involving all lobes; bilateral otitis media	
9	12/20/23	50 ♂ White	Headache, vomiting, irrational 1 day; skull fracture 1 year ago	Suspect meningitis	3	Comatose	14,500 W. B. C., few pneumococci	XXII	+	+	0	0	20 Gm.	400,000 units	No autopsy	
10	12/11/23	51 ♂ White	Lobar pneumonia 10 days; stiff neck 1 day	Lobar pneumonia; suspect meningitis	8	Practically moribund	1,500 W. B. C., few pneumococci	XXIII	+	+	250 cc.	18.5 Gm.	00 Gm.	0	Extensive purulent leptomeningitis, vegetative endocarditis; pneumonia involving all lobes	
11	2/8/24	50 ♂ White	Admitted in coma; no history	Suspect meningitis	2	Coma	Purulent; 25,000 W. B. C., intra-extracellu-lar diplococci	IX	+	Negative	0	0	15 Gm.	218,000 units	No autopsy	
12	2/16/24	63 ♂ White	Onset 1 days ago of chill, fever, cough headache and stiff neck	Suspect meningitis	2	Coma	Purulent; 47,000 W. B. C.	Not typed	Not done	Not done	0	4 Gm. intravenously	0	0	Suppurative basilar pneumococcal meningitis; focal bronchopneumonia of both lower lobes; case was mistaken for epidemic meningitis; received 100,000 units of meningococcus antitoxin intravenously	
13	3/13/24	16 mo. ♂ White	Pertussis just 6 weeks; irritative 3 days; fever and convulsions	Suspect meningitis	8	Coma; temperature 100 F.	3,800 W. B. C., intra-extracellu-lar diplococci	X	+	0	250 cc. daily	0	24 Gm.	0	Diffuse suppurative leptomeningitis; confluent bronchopneumonia; bilateral otitis; thrombosis of left middle cerebral vessels	
14	4/1/24	32 ♂ Negro	Head injury 3 months ago; headache 4 weeks; dizziness and stiff neck 3 days; history of syphilis; 1 1/2/24 spinal Wassermann negative	Suspect meningitis	18	Alert	6,000 W. B. C., many pneumococci	XXIII	+	0	700 cc.	...	87 Gm.	Not available	Abscess right frontal lobe with extension to meninges; localized meningitis; infectious hyperplasia of spleen, cloudy swelling of liver and kidney; fatty changes in liver	
15	10/4/24	41 ♂ White	Transfer from another hospital with diagnosis: epidemic meningitis; received there 1 cc. antimeningococcus serum intracranially; same amount intraspinally	Epidemic meningitis	1	Terminal	Purulent; many gram-positive intra- and extracellu-lar diplococci	XVIII	+	+	0	8 Gm. intravenously	0	0	0	No autopsy; this case of pneumococcal meningitis was mistakenly treated as epidemic meningitis

sodium salt) and specific antipneumococcus rabbit serum there were seven recoveries.

2. In the period covering these cases, more patients were admitted to the Cook County Hospital with pneumococcic meningitis than with meningococcic meningitis. The old teaching that purulent meningitis should be treated as meningococcic meningitis until proved otherwise is entirely outmoded. A vigorous search for the etiologic agent must be started at once and pursued until the organism is determined. Pending that time, sulfapyridine by mouth or its sodium salt intravenously should be given in large doses, unless hemolytic streptococci are strongly suspected, in which case sulfanilamide may be the better chemotherapeutic agent.

3. The best prognosis in cases of meningococcic meningitis is in so-called primary cases, i. e. those unassociated with other demonstrable pneumococcic lesions. The worst prognosis is in those cases associated with pneumococcic endocarditis and/or extensive pneumonia.

4. In addition to vigorous chemotherapy and serum therapy, surgical drainage of focal lesions, care to maintain an adequate fluid and caloric intake and occasionally blood transfusions are of the utmost importance.

Clinical Notes, Suggestions and New Instruments

MORGAN'S BACILLUS SEPTICEMIA

REPORT OF A CASE AND REVIEW OF EXTENT OF PATHOGENICITY OF THE ORGANISM

E. J. PULASKI, M.D., AND G. W. DEITZ, M.D., PHILADELPHIA

In 1906 Morgan isolated, from the stools of infants with "summer diarrhea," a previously undescribed gram-negative bacterium, Morgan's bacillus No. 1, which he considered of possible etiologic significance. Numerous papers have appeared since, denoting the pathogenicity of this organism not only in gastrointestinal disturbances but in other conditions as well.

The purpose of this paper is to present a fatal case of Morgan's bacillus septicemia, to record the failure of sulfanilamide and sulfapyridine therapy and to review some of the literature on Morgan's bacillus infections.

Septicemias due to *Bacterium morgani* are rare. Morgan grew the organisms from the heart blood taken after death from three children with summer diarrhea. Kendall, Day and Bagg cultured *Bacterium morgani*, also the Shiga bacillus, *Bacillus alkaligenes* and streptococci from the blood two days before death in a case of infantile diarrhea (antemortem invasion?). Probably the first recorded case of sepsis is that of Magath and Jackson, who obtained positive blood and feces cultures of *Bacterium morgani* in a fatal case of ulcerative colitis. The blood serum agglutinated the organisms in a 1:40 dilution. Thjotta obtained positive blood cultures and agglutination reactions in a fatal septicemia consequent upon *Bacterium morgani* empyema of the gallbladder. King isolated the organisms from the blood and lateral sinus in a case of mastoiditis with sinus thrombosis. Havens and his co-workers recorded six positive blood cultures in a series of forty-nine cases of a paratyphoid-life fever and listed two deaths. Specific antibodies could be demonstrated in the blood in most cases. D'Aunoy and Gittins and Hawksley also reported one case each of a typhoid-like fever with *Bacterium morgani* bacteremia.

Morgan's bacillus has been considered of etiologic relationship to infant diarrhea and dysentery. On the other hand the organism has been found in samples of soil and water and in the feces of healthy persons, and it has been recovered from many species of animals. However, it can be pathogenic in man and has been identified in cholecystitis (Thjotta) colitis (Thjotta, Magath and Jackson), mastoiditis (Dick, Dick and Williams, King, Sutton), meningitis (Gittins and Hawksley, Mitchell, Bier and Lange), peritonitis (Neter and Goodale), pyelitis (Jervell, Waaler, D'Aunoy, Riding), chronic discharging wounds (Whittingham, Fasting). It has been demonstrated in conjunction with mental disease (Stewart).

REPORT OF CASE

F. W., a white man aged 25, admitted to the hospital Sept. 12, 1939, was working over an acetylene torch August 21 when a hot spark flew into the left ear. He was seen almost immediately in the dispensary of this hospital, and inflammation of the external auditory canal (attendant on burn) was noted. Butesin picrate ointment was applied. Four days later he was still complaining of pain, although the inflammation had receded considerably. He was not seen again until seventeen days later (September 11), when he returned complaining of increasingly severe pain over the entire left side of the head and neck but especially in the left ear, which, he stated, discharged watery material from time to time. He also complained of weakness, occasional dizziness, a feeling of heaviness over the eyes and poor appetite. The temperature was 102.2 F. An extensive inflammatory process of the entire left external auditory canal was observed. Continuous hot wet compresses were advised, but since there was no appreciable improvement in twenty-four hours the patient was admitted to the hospital.

The past history revealed no previous disease of the ears. Because of the pain in the ear he had the left upper second and third molars extracted at another hospital the week before admission.

On examination the patient was toxic and apathetic, complaining of pain in the left ear and of a heavy aching over the eyes. The temperature was 103.2 F. There were a slight unproductive cough and profuse sweating. The left upper alveolar process showed evidence of recent extractions of teeth. The pharynx was slightly injected, and the tongue was coated. There was an extensive cellulitis of the entire left external auditory canal, with a small amount of thin watery foul-smelling discharge.

Tenderness was present over the ear anteriorly but not over the mastoid. The tympanic membrane could not be visualized. There was no regional lymphadenopathy. Examination of the heart, lungs, abdomen and extremities was negative. Ophthalmoscopic examination revealed blurring of both disk margins. Neurologic examination was entirely negative. The clinical impression was otitis externa with possible mastoid or intracranial involvement.

The leukocyte count was 8,200, with 92 per cent neutrophils. The erythrocyte count was 4,000,000 and the hemoglobin level 80 per cent. The urine was normal. Throat culture yielded hemolytic and nonhemolytic streptococci and *Staphylococcus albus*. Examination of the spinal fluid was negative. The dynamic factors were normal. Culture of the fluid remained sterile. The blood Wassermann reaction was negative. Culture of the material discharging from the left ear yielded a gram-negative motile bacillus that did not ferment lactose. Culture of blood taken a week after admission gave an abundant growth of a gram-negative motile rod, identical with that obtained from the ear. *Bacillus typhosus* antiserum did not agglutinate this organism.

Agglutination tests of the patient's blood with *Bacillus typhosus*, *Bacillus paratyphosus* A and B, *Bacillus proteus* X 19 and the *Brucella* antigens were negative on four occasions.

Roentgen examination of the mastoids showed diffuse clouding suggestive of chronic mastoiditis on the left side. X-ray examination of the paranasal sinuses and chest was negative. Examination of the teeth showed rarefaction around the root of the first upper left premolar.

Compresses and irrigations of the ear were begun, and the patient was given sulfanilamide. The pain in the head and

The authors were assisted in this case by Drs. W. L. C. Spaeth and S. Sugarman.
From the Departments of Medicine and Clinical Laboratories, the Frankford Hospital.

ear was so severe that continued administration of opiates was necessary for relief. The day following admission (September 13) he had a chill lasting ten minutes with an abrupt rise of temperature. The cough became more annoying, and signs of bronchitis were present. Anorexia and vomiting were pronounced. The temperature varied from 99 to 103 F., but the pulse rate consistently remained below 90 per minute. Physical and mental exhaustion progressed.

As the cellulitis of the ear gradually subsided, the discharge became more copious and fetid. When it became possible to visualize the tympanic membrane, a pinpoint perforation of the superior posterior quadrant was seen. However, there was no bulging, and the discharge appeared to originate entirely from the canal wall. At this time the anterior cervical nodes became palpable and tender. The patient's serum agglutinated Morgan's bacilli in a 1:160 dilution.

September 17 he had another severe chill and began complaining of soreness of the left side of the mouth. A localizing inflammation around the first upper left premolar was found. September 20 he had a chill about fifteen minutes in duration. The eyegrounds revealed the same blurring of the nerve heads found previously, with a hemorrhagic area above the disk on the right side. Spinal fluid examination was again entirely negative.

The patient became increasingly stuporous. The skin and scleras were jaundiced. He complained of generalized aching with severe sweats.

The cough increased. September 24, twelve days after admission, he complained of severe pain in the right side of the chest. Physical examination revealed diminished breath sounds in the right lower lobe. That evening he had a shaking chill and the temperature rose to 105.3 F. The cough became more constant, and productive. Sputum examination on three occasions revealed the presence of many pus cells, staphylococci, streptococci, pneumococci (nontypable) and gram-negative bacilli. Blood culture gave an abundant growth of Morgan's bacilli. The blood serum agglutinated *Bacterium morgani* antigen to a titer of 1:320. Roentgen examination of the chest revealed pneumonia of the right lower lobe. The leukocytes numbered 28,000 and the erythrocytes 3,200,000. An indirect blood transfusion (500 cc.) was given. The next few days he had several shaking chills. Sulfapyridine was given, without apparent benefit. The jaundice deepened. The sweating was more profuse and the mental confusion was worse.

September 30, eighteen days after admission, pain developed in the left side of the chest, and physical signs indicative of pneumonia in the left lower lobe were found. The left ear began to discharge the same foul material. The patient became more toxic and irrational. The blood serum agglutination with *Bacterium morgani* was only 1:40 on October 1. October 2 he complained of pain in the neck along the anterior border of the sternocleidomastoid muscle, which was tender to palpation. A swelling appeared, and four days later 6 ounces of thin grayish foul-smelling pus was removed from the abscess. This material yielded a pure culture of *Bacterium morgani*. At the same time, a small abscess around the upper left first molar was opened. Only *Staphylococcus aureus* was obtained on culture of the pus. The neck continued to drain freely. Expectoration of foul-smelling sputum was constant. He became progressively worse and died October 23. *Bacterium morgani* was never isolated from any of the samples of stools or urine examined.

On postmortem examination, the changes of interest were chiefly in the head and chest. The brain was edematous and congested, but no evidence of an inflammatory process was found in the meninges. The lateral sinuses were explored from the torcular Herophili to the jugular bulb, and there was no evidence of thrombi nor of thrombophlebitis. Cultures remained sterile. The left mastoid cells, when opened, contained some exudate which when cultured showed the presence of an anaerobic nonhemolytic streptococcus but no Morgan's bacilli. On opening the chest, both pleural cavities contained large quantities of foul-smelling mucopus. Both lungs were riddled with abscesses of various sizes both on the exterior and on the interior of the lungs. One large abscess had ruptured into

the left pleural cavity. Both lungs showed dense adhesions to the chest wall. The pus yielded a pure culture of *Bacterium morgani*. The heart was soft and flabby. Culture from the heart blood also yielded Morgan's bacilli. The intestine showed no inflammation, and the peritoneal cavity was grossly normal. The kidneys were swollen, flabby and edematous and suggested toxic nephrosis.

BACTERIOLOGY

The organism is a gram-negative aerobic nonsporing rod from 1 to 3 microns long, motile when freshly isolated. On frequent subculture at 37 C. motility is greatly diminished, but the organisms remain actively motile if grown at 20 C. They are easily cultivated on ordinary laboratory mediums. When freshly isolated, colonies show a tendency to swarm and in this respect resemble *Bacillus proteus*. There is a characteristic strong fecal odor, which is lost after subculture. Later generations form colonies not unlike *Bacillus coli*. Dextrose, fructose and galactose were fermented with the production of acid and gas as was trehalose. There was no action after thirty days on arabinose, rhamnose and xylose, lactose, sucrose and maltose, mannitol, sorbitol, dulcitol, inositol and salicin. Indole and hydrogen sulfide were formed abundantly. Nitrates were not reduced. Litmus milk was turned slightly alkaline. Gelatin was not liquefied. The organism acts on sheep red cells with the production of methemoglobin.

These observations are essentially the same as reported by Jordan, Crawford and McBroom in a study of many strains of *Bacterium morgani*.

SUMMARY

1. A fatal case of sepsis was apparently due to Morgan's bacillus, with the external auditory canal as the probable port of entry. Specific agglutinins were demonstrated in the blood stream. Morgan's bacillus was isolated post mortem from the heart blood and the abscesses in the lungs.

2. Sulfanilamide and sulfapyridine therapy were of no benefit.

3. A review of the literature denotes the extent of the infectiousness of the organism.

MENINGITIS EPIDEMIC AMONG NAVAJO INDIANS

SIDNEY E. SEID, M.D., CHIN LEE, ARIZ.

Although many¹ claim that meningococcic meningitis usually strikes only one member of a family, this did not hold true during a recent epidemic on the Navajo Reservation. Of twenty-eight patients seen at the Chin Lee General Hospital, in twenty-four instances there was a close family relationship to another patient or patients while in only four instances were the patients the only members of the family to contract meningococcic meningitis.

Since we saw multiple cases in the family early in the epidemic, whenever a Navajo contracted meningitis we urged that the younger members of the family be brought to the hospital for fourteen days' observation and prophylactic treatment; nineteen persons from families in which meningococcic meningitis had recently occurred were admitted to the Chin Lee General Hospital and 174 to the Northern Navajo Hospital, Shiprock, N. M., for this reason. Two thirds of these persons were under 10 years of age. At the Chin Lee Hospital, those weighing less than 80 pounds (36 Kg.) received a daily total dosage of sulfanilamide of one-half grain per pound (0.032 Gm. per 450 Gm.) body weight. Those weighing more than 80 pounds received a daily total dosage of 40 grains (2.6 Gm.). At the Shiprock hospital, Dr. R. K. Setzler (who gave permission to report those cases) and Dr. Jacob Seigel gave all their patients a daily total dosage of one-half grain per pound of body weight. At both hospitals this drug was continued for fourteen days. Fourteen days was chosen because most observ-

ers agree that the incubation period of meningococcic meningitis is less than fourteen days.

None of the 193 persons who received sulfanilamide as a prophylactic developed meningococcic meningitis while taking the drug. Two of the 193 developed meningococcic meningitis approximately one month after discontinuing the drug. The remaining 191 did not develop the disease.

We can only estimate the rate of incidence in this epidemic because we know that not all cases that occurred were brought to our attention. The most accurate count that has been made for the areas concerned in the epidemic showed a population of 11,000. The physicians in the area know of ninety-two cases. This gives an approximate incidence of one case to 120 of population. This is a very high rate of incidence, since one case to 800 population is considered epidemic.²

One of the patients who received prophylactic treatment was a nursing aged 1½ months whose mother had meningococcic meningitis. The infant suckled at her mother's breast up to the second day of illness and thereafter was in intimate contact with her mother and in less intimate contact with other patients with the disease. That the infant did not become ill may have been because (a) the child was actively immune, (b) the child was passively immune, (c) the child escaped contagion, or (d) sulfanilamide protected the child.

At 1½ months of age it is possible, but unlikely, that the child had developed an active immunity. It seems unlikely too that the child was passively immune, because it is generally agreed that the passive immunity displayed by infants is derived from the mother³ and in this instance the mother demonstrated her lack of immunity by contracting the disease. However, instances of mothers who were susceptible to diphtheria or scarlet fever while the nursing was immune have been reported.⁴ As to the child escaping contact with meningococci, any one observing the intimate contact between mother and child before and after the diagnosis was made would dismiss that possibility. If one reasons by exclusion, the possibility of sulfanilamide having protected the child grows more likely as the other possibilities seem less likely, and especially so since it has been demonstrated that sulfanilamide has curative value in cases of meningococcic meningitis.⁵

It is possible that in a group of 193 persons selected at random none of them might contract meningitis in any epidemic during a fourteen day period, although I feel strongly that this particular group of persons had far more possibility of contracting the disease than is usual because of their concentrated exposure and the higher rate of susceptibility in the residents of the Navajo Reservation at this time. This would seem especially true since the epidemic showed a strong tendency to affect successive members of the same family in a short period of time.

SUMMARY

In an outbreak of meningococcic meningitis on the Navajo Reservation the disease tended to affect several members of the same family.

This was a very severe epidemic.

Nothing in this study would indicate that sulfanilamide in moderate doses is valueless as a prophylactic for meningococcic meningitis during the time it is being administered.

Qualifications Necessary for a Flight Surgeon.—The qualifications necessary for a properly trained and successful flight surgeon are many and exacting. As in any other specialty, aviation medicine should be built on a solid foundation of general medical knowledge. An intense interest in any one specialty of general medicine is not desirable, owing to the narrow outlook which usually accompanies such an interest. A well rounded, many-sided man is much to be preferred.—Armstrong, Harry G.: *Principles and Practice of Aviation Medicine*, Baltimore, Williams & Wilkins Company, 1939.

Special Clinical Article

USE OF SULFANILAMIDE AND RELATED COMPOUNDS IN DISEASES OF INFANCY AND CHILDHOOD

CLINICAL LECTURE AT NEW YORK SESSION

BENJAMIN W. CAREY, M.D.

DETROIT

The advent of the sulfonamide compounds has probably had a more favorable effect on the course of many infectious diseases in pediatrics than in any other field of medicine. This paper will present as briefly as possible the indications for the use of the various drugs, the results of treatment, dosage and methods of administration of the sulfonamide compounds, contraindications to chemotherapy, and toxic manifestations of the drugs in infants and children.

BETA HEMOLYTIC STREPTOCOCCUS INFECTIONS

Erysipelas.—Response to therapy has been dramatically favorable in this type of infection. A reduction in the mortality of patients under 2 years of age from approximately 35 per cent to 5 per cent has occurred in most hospitals in which erysipelas is treated. The majority of deaths has occurred in cases of overwhelming infection in less than twenty-four hours after admission to the hospital. More experience has been gained with sulfanilamide, but favorable results have been observed with sulfapyridine and sulfathiazole. Sulfanilamide is probably the drug of choice because of its rapid absorption and its ease of administration.

Respiratory Infections.—Response to chemotherapy in infections of the upper respiratory tract due to the beta hemolytic streptococcus such as rhinitis, pharyngitis, tonsillitis, sinusitis and otitis media has been unpredictable in many instances. However, if the infection is suspected or proved to be due to the beta hemolytic streptococcus, routine administration of sulfanilamide is desirable. Complications may be averted, especially mastoiditis, which may be prevented or aborted with prompt and effective administration of the drug. Present experience suggests that sulfapyridine or sulfathiazole is as effective as sulfanilamide in this group of infections.

Bronchitis, Pneumonia and Empyema.—Experience has been somewhat limited in this group of infections, but good results with chemotherapy have been observed. It is doubtful whether the incidence of surgical procedures has been materially reduced in cases of empyema by chemotherapy, but the course of the process may be shortened in certain instances and a spread of the pneumonia to the opposite lung may be prevented. Sulfathiazole is probably the drug of choice in this group because of the possibility of a mixed infection with the pneumococcus or the staphylococcus.

Septicemia.—Prompt sterilization of the blood stream and improvement in the lesion responsible for the septicemia has occurred in the majority of cases following chemotherapy. Other therapeutic measures such

From the Children's Hospital of Michigan and the Department of Pediatrics, Wayne University College of Medicine.

Read in the Symposium on Chemotherapy, General Scientific Meetings, at the Ninety-First Annual Session of the American Medical Association, New York, June 11, 1940.

The antipneumococcus rabbit serum used in cases of pneumococcal infection was furnished by the Lederle Laboratories, Inc., Pearl River, N. Y., and the sulfathiazole was supplied for clinical trial by the Squibb Institute for Medical Research, Dr. George A. Harrop, director, New Brunswick, N. J.

as blood transfusions and proper surgical intervention must not be overlooked or neglected. Sulfapyridine or sulfathiazole seems as effective as sulfanilamide.

Scarlet Fever.—Present experience indicates that chemotherapy combined with antitoxin or convalescent serum is the treatment of choice for most patients with scarlet fever. The drugs have no effect on the toxic manifestations of the disease but are responsible for the reduction in the number of complications due to invasion of the beta hemolytic streptococcus from the throat. Sulfanilamide seems to be the drug of choice, although favorable effects have been observed with sulfapyridine.

Meningitis.—Chemotherapy has been effective in bringing about a marked reduction in mortality due to beta hemolytic streptococcus meningitis. Prior to chemotherapy the mortality was nearly 100 per cent, and this has been reduced to approximately 15 per cent, according to a recent summary.¹ It is desirable to institute intensive treatment with oral, parenteral and intrathecal medication in this type of meningitis, and sulfanilamide is the drug of choice because of its greater diffusibility and the variety of methods for its administration. Sulfathiazole should not be used in meningeal infections, as its concentration in the spinal fluid reaches only from 10 to 30 per cent of that in the other body fluids (table 1).

Osteomyelitis.—In osteomyelitis due to the beta hemolytic streptococcus chemotherapy should always be instituted. The response to treatment may be unpredictable, but in acute cases of septicemia the infection may be more rapidly localized, the fever reduced and the blood sterilized. Occasionally the chronic form of the disease may be cured with chemotherapy.

Peritonitis.—Considerable disagreement exists as to the most effective plan of treatment of primary beta hemolytic streptococcus peritonitis. Early surgical drainage plus chemotherapy versus chemotherapy alone divides opinion among surgeons and pediatricians. Possibly no routine rule should be followed but each case should be individualized and effective measures adopted as the occasion demands. Undoubtedly chemotherapy has aided in lowering the fatality rate and complications in this form of infection. Too few cases have been treated to evaluate properly the effect of sulfapyridine or sulfathiazole or to compare these compounds with sulfanilamide.

STREPTOCOCCUS VIRIDANS INFECTIONS

Subacute Bacterial Endocarditis.—Although a few reports exist of patients with subacute bacterial endocarditis cured by chemotherapy, it is generally agreed that the most to be gained is a temporary improvement of the patient's condition and sterilization of the blood. Certainly no definite curative effect on the underlying pathologic condition has been demonstrated.

Septicemia.—Septicemia other than that accompanying endocarditis has responded favorably to chemotherapy. Sulfanilamide or sulfapyridine seems to be equally effective in bringing about a rapid sterilization of the blood.

Meningitis.—Cases of meningitis due to *Streptococcus viridans* are rare, but there are a few reports of favorable results with chemotherapy. I have observed three patients under 2 years of age with this type of meningitis who rapidly recovered following intensive treatment with sulfapyridine.

PNEUMOCOCCIC INFECTIONS

Pneumonia.—Chemotherapy of pneumococcic pneumonia of infants and children has definite advantages over serum therapy: 1. Sputum typing of infants and children is difficult and more liable to error than of adult patients. 2. The finding of more than one type of pneumococcus in the sputum is not uncommon and is confusing if serum therapy is contemplated. 3. The administration of intravenous serum is a difficult procedure with infants and small children. In my experience pneumonia has been a relatively mild disease in the past two winters, which makes evaluation of specific therapy difficult. At the Children's Hospital of Michigan² it was found in the winter of 1938-1939 that the use of either sulfapyridine or specific antipneumococcus rabbit serum as compared with a series of untreated controls had the following effects: (1) reduction of the fatality rate, (2) reduction in the duration of the disease and subsequent period of hospitalization and (3) reduction in the incidence of complications such as meningitis, otitis media and mastoiditis, and empyema. During the past winter combined treatment with sulfapyridine or sulfathiazole and specific antipneumococcus rabbit serum has been compared with chemotherapy alone in the treatment of

TABLE 1.—Sulfathiazole: Blood and Spinal Fluid Concentrations (Simultaneous Samples)

Age	Date	Blood, Mg. per 100 Cc.	Spinal Fluid, Mg. per 100 Cc.
6 mos.	Case 1		
	April 23	6.4	2
	April 24	5.6	1.2
	April 26	4.5	0.8
10 yrs.	Case 2		
	May 9	3.4	0.8
	May 11	3.5	0.6
	May 14	5.6	0.4
	May 16	6.5	1.0

pneumococcic pneumonia. The fatality rate has been so low that no statistical differences could be found. However, in the cases in which serum combined with sulfapyridine or sulfathiazole was given it was observed that the temperature became normal about eighteen hours sooner after treatment was started than when the drugs alone were administered. In a group of cases therapy was also followed this year with the Francis test (type specific capsular carbohydrate substance) and it was observed that the cutaneous reaction after chemotherapy alone was quite irregular or remained negative even though a favorable response to the drug had occurred. This observation was correlated with the recurrence of the same type of pneumonia within two to three weeks in a group of six patients who were treated with sulfapyridine. In my experience sulfathiazole is as effective as sulfapyridine in cases of pneumococcic pneumonia. It is desirable to type all cases and to administer specific antipneumococcus rabbit serum to any patient with bacteremia, with involvement of large areas of lung or with extreme toxicity.

Empyema.—Chemotherapy has little effect on the course of pneumococcic empyema and the usual methods of surgical drainage need to be instituted. In the event that pneumonia is present in the opposite lung, or the patient is quite toxic with a high fever, administration of sulfapyridine or sulfathiazole may be desirable.

Otitis Media.—Chemotherapy with sulfapyridine or sulfathiazole should be instituted in the event that the pneumococcus is cultured from an infection in the

1. Kolmer, J. A.: Progress in Chemotherapy of Bacterial and Other Diseases, Arch. Int. Med. 65: 671 (April) 1940.

2. Carey, B. W., and Cooley, T. B.: J. Pediat. 15: 613 (Nov.) 1939.

middle ear. This might be an argument for the administration of sulfapyridine or sulfathiazole rather than of sulfanilamide to all patients with otitis media.

Meningitis.—Reports may be found of cures of this type of meningitis with both sulfanilamide and sulfapyridine with and without the addition of specific serum. The desirable method of treatment is to administer adequate doses of sulfapyridine, intravenous anti-pneumococcus rabbit serum and intrathecal serum plus complement. However, good results will be obtained only in cases which are diagnosed and treated early.

Peritonitis.—In primary peritonitis due to the pneumococcus, chemotherapy has played an effective part. As with primary beta hemolytic streptococcus peritonitis it is advisable to individualize the case and not follow a routine rule about incision and drainage versus no surgery. Because of the greater effectiveness of sulfapyridine against the pneumococcus and action equal to sulfanilamide against the beta hemolytic streptococcus, it is advisable to administer sulfapyridine or sulfathiazole to a patient with primary peritonitis until such time as the exact bacterial diagnosis is made.

MENINGOCOCCIC INFECTIONS

Septicemia.—Excellent results have been reported with the use of sulfanilamide in sterilizing the blood in chronic meningococcemia. The results with sulfapyridine have been favorable but few cases have been reported.

Meningitis.—Many rapid cures have been reported following the use of sulfanilamide in meningococcic meningitis. In fact, results have been as good with the drug alone as with combined serum and sulfanilamide therapy. However, it is well known that certain strains of the meningococcus are resistant to sulfanilamide. While less experience has been obtained with sulfapyridine, reports in the literature and my experience lead me to believe that this drug is as effective as sulfanilamide. Sulfanilamide may be the drug of choice because of its greater diffusibility throughout the body and the ease and variety of methods of its administration. The failure of sulfathiazole to reach adequate concentrations in the spinal fluid should again be emphasized; this drug should not be administered for the treatment of meningitis. The question of anti-meningococcus serum in addition to chemotherapy cannot be fully answered from my past experience. It has been my policy to reserve the use of intrathecal serum for patients who do not respond rapidly with sterilization of the spinal fluid and a reduction of the spinal fluid leukocyte count after from thirty-six to forty-eight hours of chemotherapy. In severe fulminating cases in which there is evidence of septicemia from the presence of multiple petechiae, it is advisable to initiate treatment with both intravenous meningococcus antiserum and parenteral sulfanilamide solution by hypodermoclysis or intravenously.

GNOCOCCIC INFECTIONS

Ophthalmia Neonatorum.—There is no doubt as to the efficacy of chemotherapy in reducing the complications and duration of the disease in this type of gonococcic infection. Michels³ in 1938 showed in a series of fifteen patients treated at the Children's Hospital of Michigan that complications were reduced to zero and the average period of hospitalization was reduced from 28.5 days to 5.8 days. Since this report an equal number of patients has been treated with the

same excellent result. Equally favorable results have been obtained with sulfapyridine.

Vulvovaginitis.—In general, the reports in the literature have shown similar results from chemotherapy in vulvovaginitis as in adult gonococcic infections. My experience has been limited to a small group of ten cases, in seven of which there was a rapid and permanent cure with sulfanilamide. The drug had little influence on the other three patients. From unpublished reports better results have been observed by combining endocrine therapy with sulfanilamide. Sulfapyridine has equally good effect and may even be superior to sulfanilamide, although few cases have been reported in which this compound was used.

STAPHYLOCOCCIC INFECTIONS

My experience with sulfanilamide and sulfapyridine in the common staphylococcic infections encountered in pediatrics, namely septicemia, osteomyelitis, pneumonia, furunculosis and other types of cutaneous infections, has convinced me that neither drug had much effect. With the advent of sulfathiazole new hope was raised for a form of chemotherapy with definite antistaphylococcus action.

Cutaneous Infections.—My experience with this group consists of two infants with infected eczema, two patients with furunculosis, one patient with impetigo and two patients with deep abscesses. In general the results were not dramatic but it was concluded that the drug probably had a definite effect in reducing the temperature and shortening the period prior to incision and drainage. According to the few reports in the literature at this time the experience of others has been similar.

Septicemia.—Six patients with staphylococcic septicemia were treated with sulfathiazole. Two of these were infants with acute ethmoiditis and septicemia, both of whom died within forty-eight hours of admission to the hospital. One patient with pneumonia and staphylococcic septicemia received only forty-eight hours of sulfathiazole therapy during seven days of hospitalization, an amount considered inadequate, and this patient died. Three patients had a staphylococcic septicemia accompanying acute osteomyelitis. The response to the drug was dramatic, with sterilization of the blood and reduction of the temperature to normal after twenty-four hours of chemotherapy. However, incision and drainage of the bone abscess was necessary.

Pneumonia.—Four of six patients with staphylococcic pneumonia, other than the one with septicemia and pneumonia mentioned previously, who were treated with sulfathiazole had a prompt reduction in fever and the duration of the disease seemed to be shortened. One patient with staphylococcic empyema was treated with sulfathiazole and no change was observed either on the temperature course or on the accumulation of fluid in the pleural space.

HAEMOPHILUS INFLUENZAE INFECTIONS

Septicemia.—Septicemia caused by a smooth virulent strain of *Haemophilus influenzae* has not responded to chemotherapy in my experience. Infection caused by less virulent rough strains may be effectively treated with chemotherapy alone. However, it is advisable in all cases to combine therapy with sulfanilamide and *Haemophilus influenzae* serum.

Meningitis.—Likewise, meningitis caused by smooth virulent strains of *Haemophilus influenzae* is little influenced by chemotherapy alone, whereas reports exist

3. Michels, M. W.: J. Pediat. 13: 527 (Oct.) 1938.

of cures of meningitis caused by less virulent strains. Best results in the severe infections have been obtained by combined therapy with doses of sulfanilamide large enough to obtain spinal fluid concentrations of free sulfanilamide of from 20 to 25 mg. per hundred cubic centimeters and intravenous serum and intrathecal serum plus complement. Occasionally a dose of 4 grains (0.26 Gm.) per pound (450 Gm.) has been administered to maintain such a concentration. My experience with combined chemotherapy and Haemophilus influenzae serum has been disappointing. In the past two years I have treated ten patients with combined therapy, and the fatality rate has been 80 per cent in this group.

INFECTIONS OF THE URINARY TRACT

In the absence of marked anatomic abnormalities of the urinary tract or infections of long standing with diminution of kidney function, chemotherapy has played one of its most important parts. In fact, with the exception of mandelic acid, sulfanilamide and sulfathiazole have placed all other urinary antiseptics in the position of historical interest.

Infections Due to the Bacillus Coli Group of Bacteria.—Sulfanilamide shows its best effect in this group of organisms, which fortunately is the most common cause of infection in the urinary tract. Prompt reduction of the leukocytes in the urinary sediment and sterilization of the urine is the usual course with chemotherapy. The effective concentration of free sulfanilamide in the urine is between 75 and 150 mg. per hundred cubic centimeters. Sulfapyridine has not been as effective as sulfanilamide. However, sulfathiazole seems to be similar to sulfanilamide in therapeutic action.

Infection Due to Bacillus Proteus.—Sulfanilamide and sulfathiazole are the only chemotherapeutic agents effective in this type of infection, the chief characteristic of which is the production of a highly alkaline urine following proteolytic activity of the organism.

Infection Due to the Staphylococcus.—Sulfanilamide has not been as effective in this type of urinary infection. Unpredictable results have been obtained in treatment. Sulfathiazole seems to be more reliable as a chemotherapeutic agent in staphylococcal infection of the urinary tract.

Infection Due to Streptococcus Faecalis.—Both sulfanilamide and sulfapyridine are without value in sterilizing the urine in infections caused by Streptococcus faecalis. Mandelic acid was the only effective drug until the advent of sulfathiazole, which has given promise of producing sterilization of the urine when the infecting organism is Streptococcus faecalis.

BRUCELLA INFECTIONS

Reports are at variance on the effect of sulfanilamide on undulant fever. My experience has been limited to a group of three patients in the acute stage of the disease when Brucella abortus could be cultured from the blood. In this small group of patients the sulfanilamide had no demonstrable effect on either the temperature or the course of the disease.

TYPHOID-DYSENTERY INFECTIONS

I have been unable to find any change in the symptoms or course of typhoid with the usual dose and blood levels of sulfanilamide or sulfapyridine. In dysentery caused by the bacilli of Sonne and of Flexner, sulfanilamide or sulfapyridine had no effect on the fever, course of the disease or cultures of the stool. I have had no experience with sulfathiazole in these infections.

TRACHOMA

Sulfanilamide has been found to have a favorable effect on trachoma in bringing about an amelioration of symptoms and allowing healing to take place. My experience has been small but agrees with that of others as reported in the literature.

INFECTIONS IN WHICH CHEMOTHERAPY IS CONTRAINDICATED

Rheumatic Fever.—It has been adequately proved that sulfanilamide has no effect on rheumatic infections, and in fact exacerbations of the disease have been observed during administration of sulfanilamide.

Diphtheria.—This should be emphasized because of the common and desirable practice of administering sulfanilamide to patients with throat infections. One should not forget to culture material from these throats for the presence of Bacillus diphtheriae before starting chemotherapy and to administer diphtheria antitoxin if such an infection is present. There is a certain amount of evidence that sulfanilamide may be destructive to the diphtheria bacillus but that it has no effect on the toxin, and disastrous complications such as neuritis or myocarditis may occur later if antitoxin is omitted.

Virus Infections.—There is sufficient evidence to conclude that the sulfonamide compounds have no effect on infections caused by a filtrable virus such as the common cold, epidemic influenza, poliomyelitis and the exanthemas measles, chickenpox and smallpox.

DOSAGE AND METHODS OF ADMINISTRATION

Certain general principles concerning chemotherapy need to be emphasized. In all cases it is desirable to know the body weight and calculate the dosage on this basis. It is usually advisable to initiate treatment with a dose larger than any of the maintenance doses. A favorable response to therapy will usually occur within two to four days from the onset of chemotherapy, and prolonged medication in the hope of a delayed response has little to be desired.

The full dose of the drug selected should be administered for approximately forty-eight hours after a favorable response has been obtained. The dose should then be halved and maintained for a period of two or three days before the drug is discontinued. Recurrence or spread of infection is most likely to be averted if this plan is rather strictly adhered to.

I have not administered alkali with any of the sulfonamide compounds for the past two years, except with sulfanilamide for the treatment of urinary infections to maintain the urine alkaline throughout the period of chemotherapy. The results of my studies of the carbon dioxide power and the p_H of the blood of patients presenting hyperpnea during chemotherapy concur with the conclusions of Hartmann⁴ that acidosis does not result from chemotherapy and that the routine administration of alkali with the sulfonamides is unnecessary. Alkalinization of the urine of patients with urinary infection does not appear to be necessary if sulfathiazole is administered.

Nausea and vomiting following the oral administration of the sulfonamides has occasioned little difficulty in my experience. I have administered the drugs to infants by crushing the tablets in a small quantity of fluid and feeding by a teaspoon, and to children by the same method or by feeding the whole tablet with small quantities of sweetened fluids. Significant blood concentrations of the drugs have been observed even in the

4. Hartmann, A. F.: Ann. Int. Med. 13: 949 (Dec) 1939

presence of some vomiting, and unless the vomiting was continuous and severe chemotherapy was not discontinued. Frequently the vomiting was relieved by omitting the drug for one or two doses rather than discontinuing it.

Chart 1.—Relation of dose of sulfanilamide to blood level.

I have observed that the height of the blood level does not always have a direct relationship to the size of the dose during administration of both sulfanilamide and sulfapyridine. The charts show the average blood concentrations for "free" sulfanilamide and sulfapyridine compared to the daily dose of the drug. Estimations of the blood concentration of the drugs are

TABLE 2.—Sulfanilamide: Desirable Blood Level from 8 to 12 Mg. per Hundred Cubic Centimeters

1. Oral
Initial: One-half grain per pound (maximum 60 grains)
Maintenance: 1 to 1½ grains per pound in 24 hours in 4 to 6 doses (maximum 120 grains)
2. Subcutaneous: 0.8% in 0.85% saline solution
Initial: 5 cc. per pound (maximum 500 cc.)
Repeat: 3 to 5 cc. per pound at 8 to 12 hour intervals
3. Intravenous and intrathecal: 0.8% in 0.85% saline solution
Intravenous: Dilute with equal parts 10% dextrose or 0.85% saline solution (maximum 3 cc. per pound in 24 hours)
Intrathecal: 5 cc. less than volume of spinal fluid withdrawn

therefore desirable in order that the dosage may be properly adjusted.

Tables 2 and 3 outline the dosages of the drugs which are most frequently followed and the methods of administration of sulfanilamide, sulfapyridine and sulfathiazole.

TOXIC MANIFESTATIONS

Cyanosis.—Sufficient evidence has accumulated to prove beyond question that the cyanosis encountered during chemotherapy is due to the formation of methemoglobin and rarely sulfhemoglobin. For the past eighteen months at the Children's Hospital of Michigan it has been a routine procedure to obtain total hemoglobin, methemoglobin and sulfhemoglobin estimations simultaneously with the estimation of the drug concentration on the same micro blood sample by means of the photoelectric colorimeter. Ninety per cent of all patients receiving either sulfanilamide, sulfapyridine

or sulfathiazole have had amounts of methemoglobin varying from 0.5 Gm. to 3 Gm. The largest amounts have been observed in cases in which sulfanilamide was given. In addition, 5 per cent of all patients receiving the drugs have had approximately 0.5 Gm. of sulfhemoglobin in their peripheral blood samples. The amount of methemoglobin has rarely occasioned concern and was readily controlled by the administration of methylene blue orally or intravenously. This simple procedure may be indicated in cases in which there is a low total hemoglobin or in cases in which a general anesthesia is contemplated.

TABLE 3.—Sulfapyridine or Sulfathiazole: Desirable Blood Level from 4 to 8 Mg. per Hundred Cubic Centimeters

1. Oral
Initial: One-fourth grain per pound (maximum 45 grains)
Maintenance: 1-1½ grains per pound in 24 hours, in 4 to 6 doses
2. Intravenous: Sodium sulfapyridine 5% in sterile distilled water
Sodium sulfathiazole 5% in sterile distilled water
Initial: 1.25 cc. per pound (maximum 100 cc.)
Repeat: 1.25 cc. per pound at 12 hour intervals, sodium sulfapyridine 1.25 cc. per pound at 8 hour intervals, sodium sulfathiazole
3. Rectal: 5% sodium salt in sterile distilled water
Dose: 2-3 cc. per pound in 24 hours, divided in 4 to 6 rectal taps

Blood Destruction.—Acute hemolytic anemia and granulocytopenia have rarely been observed by me, although reports of a considerable incidence of hemolytic anemia exist in the literature. If either of these manifestations occurs, the drug should be stopped at once and proper corrective measures instituted, such as to increase the fluid intake and the giving of blood transfusions. Free use of transfusions of blood is a common practice in most hospitals for infants and children, which

Chart 2.—Relation of dose of sulfapyridine to blood level.

may explain the relatively low incidence of manifestations of blood destruction in this age group.

Nausea and Vomiting.—Nausea and vomiting have been encountered less frequently in chemotherapy in pediatrics than in adult practice. Sulfapyridine has produced more difficulty than sulfanilamide, but nausea and vomiting have rarely been observed in sulfathiazole therapy. In fact, patients have tolerated sulfathiazole

when previously sulfanilamide or sulfapyridine produced intense vomiting.

Cerebral Symptoms.—Headache, depression, confusion or manic states are rare in infants and children receiving chemotherapy. Occasionally in the older child a temporary depression has been observed, but rarely has it been severe enough to warrant withdrawal of the drug.

Hematuria.—Urinary concretions of acetylsulfapyridine and hematuria have been observed in cases in which sulfapyridine is being given. The incidence has been less than 1 per cent, and permanent kidney dysfunction is rare. Acetylsulfathiazole crystals and hematuria have been observed during administration of sulfathiazole.

Hepatitis and Jaundice.—A few cases of hepatitis and jaundice have been observed during chemotherapy in infants and children.

Fever and Rashes.—Fever as a toxic manifestation to chemotherapy has been observed in about 1 per cent of infants and children. Usually it has not been difficult to distinguish the fever from that accompanying the infection. It has been suggested that fever may be a forewarning of a severe toxic reaction and discontinuance of chemotherapy is advisable. I have not observed this. Various types of rashes have been observed as a reaction from all the chemotherapeutic agents. These have included morbilliform types, a diffuse erythema, urticaria and, more recently, a rash resembling erythema nodosum, as described by Haviland and Long,⁵ has been observed during therapy with sulfathiazole.

If any of the following toxic manifestations are encountered, the drug should be immediately withdrawn: acute hemolytic anemia, granulocytopenia, purpura, hepatitis and jaundice.

Unless the infection for which the drug was prescribed has not been controlled, it is advisable to discontinue therapy if any of the following toxic manifestations appear: hematuria, severe nausea and vomiting, drug fever and rashes.

PROPHYLAXIS

Surgery.—Reports of the prophylactic use of the sulfonamides in pediatric surgery are few. A few pertinent suggestions may be made for the application of this practice.

The prophylactic use of sulfanilamide prior to tonsillectomy may be considered. If a tonsillectomy is contemplated during the late convalescent stage of scarlet fever the administration of sulfanilamide before and after the operation may prevent invasion and complications from the beta hemolytic streptococcus. Tonsillectomy on patients with rheumatic infections occasionally results in a disastrous invasion by the beta hemolytic streptococcus and exacerbation of the rheumatic process. The prophylactic use of sulfanilamide as a preoperative and postoperative measure is worthy of consideration.

During the winter months when the incidence of respiratory infections is high in any children's hospital, pneumonia is occasionally an undesirable postoperative complication of both emergency and elective surgical procedures. The routine administration of sulfapyridine or sulfathiazole as part of the postoperative therapy may be seriously considered in the hope that postoperative pneumonia may be prevented.

Rheumatic Infections.—Two reports have appeared⁶ on the prophylactic administration of small daily doses of sulfanilamide (from 10 to 15 grains, or 0.65 to 1 Gm.) to patients with rheumatic infections to prevent beta hemolytic streptococcus infections of the upper respiratory tract, with which there is so frequently an exacerbation of the rheumatic process. More experience is needed to evaluate this procedure thoroughly, but it deserves consideration.

Miscellaneous.—The prophylactic administration of the sulfonamides during epidemics of beta hemolytic streptococcus infections of the throat, epidemics of scarlet fever and epidemics of meningococcal meningitis has been suggested but no wide experience with this procedure has been reported.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles were submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, the late Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. When completed, the series will be published in book form.—ED.

THE THERAPY OF ACUTE DELIRIUM (TOXIC PSYCHOSIS, FEVER PSYCHOSIS, INANITION PSYCHOSIS)

IN COLLABORATION WITH S. H. KRAINES, M.D.

Under this heading will be discussed acute symptomatic delirium, which is a more or less temporary condition of disorientation usually accompanied by hallucinatory states and often by a predominant affect of fear. It is due to disturbance in the metabolism of the brain, be this from toxemia, inanition or edema—of a reversible type so that complete recovery may occur. The therapy of delirium is the most frequent psychiatric problem facing the physician, no matter whether he is in general or in special practice. As delirium is in itself a danger to life, not only to the patient himself but also to his attendants, and as it greatly increases the patient's suffering and the difficulty of treatment and beclouds the prognosis, every effort should be bent on its early recognition. In early stages deliriums are often preventable or can be greatly ameliorated and the danger to life and limb much diminished.

One must guard against delirium in all cases of fever and of inanition, in cardiovascular and renal disorders most especially when there is edema or nitrogen retention. In cases of head injury, in cases with acute impairment of the sensory apparatus (vision or hearing) and in cases in which drugs disturbing brain function have been administered, whether bromide, opiate, hypnotic or anesthetic, and in alcoholic addicts suffering from any sickness whatever. Indeed, every chronic alcoholic addict who is seriously sick in any way or who has sustained an accident presents a potential case of delirium tremens. That he is on the verge of delirium may be assumed by the finding of tremor, apprehensive-

6. Thomas, Caroline B., and France, Richard: Bull. Johns Hopkins Hosp. 64: 67 (Jan.) 1939. Coburn, A. F., and Moore, Lucile V.: J. Clin. Investigation 18: 147 (Jan.) 1939.
Dr. Fantus died April 14, 1940.

ness and motor restlessness even without the occurrence of visual or auditory hallucinations.

Whether a patient does or does not develop delirium depends on (a) the severity of the toxemia or malnutrition and (b) the constitutional and emotional stability of the patient at the time of illness. Patients under emotional tension may develop delirium from relatively slight causes.

DIAGNOSIS

1. *Mental Symptoms.*—Deliriums tend to involve primarily the intellectual function. This is in contradistinction to the relative intactness of this function in schizophrenic and manic-depressive psychoses. The intellectual functions include orientation as to time, place and person, memory for recent and remote events, general information, ability to calculate and ability to use an adequate amount of judgment. Here again it must be remembered that these functions can be evaluated only in the light of the individual's ability before the psychosis began. The memory may be poor, calculation inefficient and judgment inadequate, and still the individual may not be delirious but may be feeble-minded or uncooperative.

The involvement of the higher intellectual functions results in a release of the more primitive mental functions, so that in these psychoses the basis personality which is ordinarily masked by inhibitions and conditioned experience tends to come to the fore almost in proportion to the degree of involvement of the cerebral cortex. It is for this reason that the various deliriums present such a wide variation in picture. The same basic pathologic condition may manifest itself in one patient as a euphoric manic illness. Another patient with this disease may be depressed; still others will present delusions of persecution and will simulate typical dementia praecox. Not infrequently these patients show a simple dementia with no particular mood change. The symptoms in themselves may vary from the muttering restlessness of the typhoid patient to that of the violent agitation and hallucinosis of the acute alcoholic addict. Often there are sleeplessness, headache, dizziness, terrifying dreams, drowsiness, incoherent statements, dull comprehension, incontinence, misidentification and forgetfulness. Marked apprehensiveness is common and may be associated with hallucinations.

2. *Signs.*—These are most important from the standpoint of differentiation of acute symptomatic delirium from chronic delirium or the psychoses of dementia paralytica, cerebral arteriosclerosis, brain tumor or cerebral syphilis and the paranoic and paranoid delusional states.

In the acute deliriums associated with other organic illnesses or fevers the patient presents the symptoms due primarily to the basic disease. The typhoid patient, the pneumonia patient, the patient with septicemia all these show the usual signs of their illness and must be treated in accordance with the underlying disease. The phenomena of advanced heart or kidney disease, of marked disturbance of the autonomic nervous system or of metabolism—be this cachexia, acidosis, alkalosis or avitaminosis, e. g. pellagra—are evident to one who looks for them, as are the characteristic signs of drug intoxication, such as alcoholism, atropinism, bromism or barbiturate poisoning.

3. *Laboratory Observations.*—The clinical examination of the delirium patient should include not only routine procedures such as urinalysis and blood count but also spinal puncture to determine the nature and

tension of the cerebrospinal fluid and special tests for drugs when those are suspected of causing the condition.

The therapy may be discussed under the headings prophylactic and causal treatment, symptomatic treatment; hypohydration treatment in cerebral edema cases, e. g. delirium tremens, and psychotherapy.

PROPHYLACTIC AND CAUSAL TREATMENT

When one realizes the fact that intoxication and exhaustion in addition to hyperpyrexia are the underlying causes of delirium, it will readily be seen that the prophylactic and the causal therapy of delirium are identical. It includes chiefly the following items:

1. Prevent hyperpyrexia (see Fever Regimen) because high temperature no matter how induced tends to produce delirium.

2. Avoid increasing the toxicosis by giving deliriant drugs and those that may interfere with the proper nutrition of the brain. The latter liability is particularly great with bromide, which should be considered contraindicated in all grave nutritional disturbances of the cerebrum, such as the delirium occurring in the later stages of typhoid. The action of bromide may be visualized as due to the bromide ion going into partnership with the chloride ion and being able to serve, almost as well as the chloride, the nutritive functions of the body with the exception of its most sensitive tissue, the nervous system. This interference with nutrition is of little consequence to the nervous system of an individual in fairly good nutritional equilibrium—excepting that it lessens irritability—unless or until about 30 per cent of the body chloride is replaced by bromide, when symptoms of intoxication are likely to supervene. In the fever patient the intoxication threshold is lower. A blood bromide of 150 mg. per hundred cubic centimeters (Wuth test¹) may be regarded as the dangerous level, though even 75 mg. may be significant. Bromide intoxication manifests itself by drowsiness, poor memory, confusion, thick speech, ataxia, tremors and delirium. A rash (acne) may or may not be present. The symptoms may persist for weeks after the blood bromide has returned to normal.

As any one of the hypnotics is capable of acting as a deliriant when given in dose insufficient to produce sleep, one must either give no hypnotic at all or give enough to produce deep sleep.

When a patient is on the verge of delirium, it is best to stop all medicine excepting that indicated by the condition present.

3. Maintain correct fluid balance. Forcing fluid to "favor elimination" must be carried out with discretion and it is contraindicated when there is a tendency to cerebral edema. This indicates hypohydration therapy, which consists of limitation of fluid intake to 1,000 cc. for the twenty-four hours, dextrose phleboclysis of from 50 to 100 cc. of 50 per cent solution, which may be repeated every eight hours, and magnesium sulfate by mouth, 30 cc. of saturated solution. This regimen tends to prevent development of the "wet brain" found so frequently on necropsy of alcoholic addicts.

In cases then in which there is no excess of cerebrospinal pressure, one may give the patient all the fluid he will take by mouth or can retain. If this amount is inadequate to maintain liberal urinary elimination, phleboclysis (5 per cent dextrose solution) should be employed. The extent to which fluid should be forced needs to be guided by the way the kidneys respond to the appeal. As long as the quantity of the urine

1. Wuth, Otto: Rational Bromide Treatment: New Methods for Its Control, J. A. M. A. 88: 2013-2017 (June 25) 1927.

increases, elimination may be assumed to be improved. When this limit is exceeded the forcing of fluid does harm. It then causes edema, latent or manifest, including cerebral edema, which may produce delirium.

In bromide intoxication and in all conditions of hypochloridemia (q. v.) sodium chloride should be freely administered, but again only up to the point of making good the deficit and improving elimination. In bromide intoxication it is not advisable to push chloride at first or until after the blood bromide has fallen to 150 mg. per hundred cubic centimeters, as chloride administration temporarily increases the blood bromide concentration, while the elimination by the kidneys remains unaffected.

4. Maintain metabolic equilibrium to the best possible degree. This demands faithful feeding from the very inception of any serious illness. The diet must cover the most nourishment the patient can take care of. An alcoholic addict who vomits may be able to retain a cup of hot milk made "hotter" by 1 cc. of tincture of capsicum. The patient may possibly be able to take cereal gruels. It must be pointed out here that special attention should be given the administration of an abundance of vitamins, especially vitamins B and C, particularly for the alcoholic addict, as it is evident that chronic alcoholism produces subvitaminosis to the extent to which the abuse of liquor interferes with or is used as a substitute for vitamin-containing food.

The suggestion has been advanced that, in addition to a carbohydrate-high diet, from 5 to 10 units of insulin be given one hour before meals not only for improving the assimilation of the carbohydrate but also for its calming effect. One must watch the patient carefully to intercept by promptly giving sugar a hypoglycemia crisis (sweats, weakening of pulse, epileptoid attacks or increase in the delirium). Acidosis (q. v.) or alkalosis (q. v.) and hyperthyroidism (q. v.) require special management. If the hemoglobin percentage is below 50, blood transfusion is indicated.

5. Maintain optimum possible cardiorenal functions. For the indicated therapeutic tactics, should heart or kidney action be insufficient, reference must be made to the *Therapy of Circulation Depression* and to the *Therapy of Uremia*.

6. Secure an adequate amount of rest and sleep. When one realizes how exhausted a healthy person feels after even one sleepless night, it is easy to understand that it is nothing less than malpractice to permit a seriously ill patient to suffer from insomnia night after night. Sleep is as important as food in the survival period. Hence we must give our patients solicitous care to secure as much sleep as possible, day or night. The sleeping patient should not be awakened for the giving of medicines or any other treatment unless this is especially ordered by the physician. To awaken a patient for the morning toilet who, after a restless night, has at last fallen asleep (as is done in a routine manner in some hospitals) is the worst kind of nursing practice.

The measures to be used for the securing of sleep have been discussed under *Therapy of Insomnia*. Here it must be pointed out that a beginning delirium may possibly be aborted by a darkened room, a reassuring nurse and an ice cap plus, if necessary, an adequate dose of hypnotic such as paraldehyde 10 cc. in water by mouth or rectum. This regimen may prevent a prolonged and dangerous delirious state.

SYMPTOMATIC TREATMENT

Protection.—In all those conditions in which delirium is likely to occur, as in every alcoholic addict who is

starving from the exclusive use of liquor, from vomiting or from intercurrent disease, the physician should look for tremor, reflex disturbances, changes in the patient's mental grasp and orientation, and in his feelings and sensations. The forerunners of delirium are continued insomnia, taciturnity and apathy or loquacity and nervous irritability, suspiciousness, anxiety and muscle twitching. When any of these are discovered and even in the absence of hallucinations or delusions he should promptly institute appropriate measures to keep the patient from harming himself or those around him.

This requires constant nursing care. A delirious patient must not be left alone even for a minute, and nothing with which he can harm himself or others should be within his reach. The treatment should be directed at making the patient less fearful. An efficient, tactful nurse who is able to speak quietly and soothingly usually is able to do more to prevent excessive activity than physical restraints. The patient's senses, impaired as they are by the toxic state, are unable to record accurately the various stimuli from without, and thus illusions (which are mistaken impressions) occur. This is particularly true in the early morning and late evening hours when the changes in light make it more likely for illusions to be experienced. It is during these particular times that the patients become more easily frightened and as a result agitated and restless. An understanding and reassuring nurse who knows how to dispel these unreasonable fears will often quiet the patient far more than sedative medication.

When a patient is absolutely determined to get up, it is often much wiser to allow him to sit up or even rise for the moment and then with gentle persistence to lead him back to bed than to have him expend a great deal more energy by struggling against the restraining persons, sheets or straps. Patients become covered with perspiration, increase their temperature and become exhausted by such struggling, using more energy than they seem to possess. It is much less exhausting for such patients, when in their anxiety, if they are allowed to sit up or even get up for the moment until their weakness causes them to relax.

The windows of all rooms in which such patients are kept should be properly guarded, since accidental suicides are not uncommon among delirious patients. The doors must be barred, since such patients may run away even as they are in their night clothes. The ideal treatment for all delirious patients is their prompt transfer to the psychopathic department or to a ward properly equipped for the care of these temporarily psychopathic patients.

Hydrotherapy is of great value, especially for the alcoholic addict. The secret of its success lies not only in the specific soothing and relaxing effect of the warm water but also in the fact that the patient is comfortable while in the bath and uncomfortably chilly the moment he tries to get out of it. Sometimes an ordinary tub bath of warm (not hot) water (never over 100 F.) for half an hour will work wonders in quieting a patient. Still better is the prolonged or continuous neutral bath with water between 96 F. if there is fever and 98 F. if there is no fever. The temperature of the water should always be a little lower than the body temperature to allow for the escape of heat from the body. These tub baths should be tried as a rule before giving sedative medication, if the condition of the patient, e. g. surgical wounds, does not contraindicate it. The medicinal sedatives are substances foreign to the human body not entering into its anabolic processes. They are poisons which must be eliminated by the emunc-

tories overstrained by the poisons already present. Often medication actually aggravates the delirium. In properly equipped "continuous bath" tubs it is possible to keep a patient for eight hours or longer. In such baths the temperature must be constantly checked and recorded so as to avoid chilling or scalding. While the patient is in the tub he should have an ice bag on his head and be given frequent sips of water. The room should be darkened, warm and quiet.

Another useful form of hydrotherapy is the "cold wet pack." The patient is placed on a table and wrapped in a sheet which has just been wrung out in water of about 65 F. and immediately afterward wrapped in warm blankets outside the sheet. The sheet will absorb much of the body temperature and the reacting warmth often has a strong soothing effect. The covering blanket may be retained after half an hour or removed, always depending, as in everything else, on the thermic and circulation reaction of the patient.

Physical restraint should be avoided if it is at all possible to get along without it. The patient moves about and acts irrationally because of the disturbed condition of his brain. Restraint causes most individuals to become antagonistic and thus more agitated and it adds to their baseless fears and actually motivates them to further activity.

Where there is insufficient help a restraining sheet may have to be used, passed across the patient and wound around the bars of the bed. Side boards, well padded to avoid bruises, are often adequate for these restless persons. The wrist and ankle straps at present in general use in many hospitals are a relic of the barbarous past, necessary as long as adequate segregation and humane protection of these patients cannot otherwise be secured. Their employment should be abolished as soon as possible. They irk the patient so much that the first thing many of them shout to any one approaching is "Say, got a knife? Cut them straps!"

Sedative Medication.—Attempts are often made to quiet patients who are delirious with all sorts of medicine, yet nothing of value is usually accomplished. The harm that comes to a patient by yelling is little when compared with the possible toxic effect of a medication that may not only fail to quiet but may actually make the patient worse. In many hospitals there is no proper provision for such noisy persons and quiet must be obtained for the other patients present. Ice bags to the head, hydrotherapy and an intelligent nurse may be able to accomplish this. If this fails, sedatives may have to be resorted to. Their use, like that of physical restraints, then becomes a necessary evil.

If absolutely demanded by the patient's need of rest, hypnotic drugs should be given only for the night, when the patient is more apt to be disturbed, and they should be administered before darkness sets in, since the latter may increase the patient's disorientation and fear. The dose must be large enough to cause sleep, and a quick acting readily metabolized and eliminated drug should be chosen.

Paraldehyde meets these requirements more nearly than any other drug. The effects set in within ten to fifteen minutes and it does not depress heart and respiration. Its toxicity is so low that 100 Gm. merely produces very prolonged sleep. It is only when the patient is under the influence of an almost fatal dose of alcohol that its administration may be dangerous, as it acts in the same way as alcohol. Its chief disadvantage is the disagreeable odor and taste and its local irritative quality. The dose in delirium is from 10 to 15 cc. given

in ice water, tea or wine. Its taste is partly disguised by compound spirit of orange (prescription 1). It may be administered by rectum (prescription 2).

Amytal sodium may be given intravenously to patients who do not respond sufficiently well to paraldehyde. It should be injected at the rate of 0.1 Gm. a

PREScription 1.—*Paraldehyde and Compound Spirit of Orange*

Rx Paraldehyde	40 cc.
Compound spirit of orange.....	10 cc.

Tablespoon in iced tea to be followed by teaspoon doses hourly until patient is asleep.

PREScription 2.—*Paraldehyde and Alcohol*

Rx Paraldehyde	40 cc.
Alcohol	40 cc.

One fourth the quantity (20 cc.) in 100 cc. of physiologic solution of sodium chloride, to be given as retention enema. To be repeated in an hour if necessary, then every two to four hours as required.

minute and a dose of from 0.5 to 1 Gm. should not be exceeded. It is obtainable in ampules containing this quantity of the salt and accompanied by an ampule containing ten times the amount of sterile distilled water in which it is to be dissolved just before administration.

Should it be undesirable to administer either of these, one might consider the possibility of synergistic medication to obtain possibly maximal sedation with a minimum of undesirable side effects. It has been customary in this hospital to give a mixture the essential ingredients of which are Chloral Hydrate (0.3 Gm.) and Tincture of Hyoscyamus (0.05 cc.) with Morphine Sulfate (1 mg.) per dose. It may be doubted that the small dose of morphine adds anything to the effect of the medicine. There are many who consider morphine in sufficient dosage to quiet the patient distinctly dangerous to delirious patients, especially to alcoholic addicts, many of whom become excited by it. It is contraindicated in delirium tremens, as it tends to raise intracranial pressure. It increases reflex excitability, which is generally excessive in these patients. The

PREScription 3.—*Compound Elixir of Chloral and Phenobarbital*

Rx Soluble saccharin	0.05 Gm.
Chloral hydrate	6.00 Gm.
Soluble phenobarbital	0.50 Gm.
Fluidextract of hyoscyamus.....	2.00 cc.
Elixir of eriodictyon (R. B. II).....	100.00 cc.

Tablespoon (15 cc.) in water as first dose, to be followed by hourly teaspoon dosage until the patient is asleep. (Hypnotic in delirium.)

combined use of morphine with barbiturate is especially to be avoided, as it may cause the patient to "forget to breathe" on account of summation of depressant action on the respiratory center. The elixir of chloral and phenobarbital (prescription 3) contains in each teaspoon one half the average official dose of each ingredient in a relatively palatable form. It might be given in tablespoon doses (15 cc.) in water to be followed by hourly teaspoon dosage until the desired effect is obtained.

HYPOHYDRATION TREATMENT

Hypohydration treatment is indicated for reduction of intracranial edema and excessive cerebrospinal fluid pressure occurring in delirium tremens as well as in some other forms of delirium. It includes:

1. Spinal drainage of from 50 to 75 cc. of fluid. This may be repeated after an interval of from six to twelve hours. The fluid must be permitted to escape very slowly.

2. Phleboclysis of sucrose solution 50 per cent; from 100 to 200 cc. or even 500 cc. may be repeated every six to twelve hours alternating with the spinal drainage.

3. Magnesium sulfate 60 cc. of a saturated solution should be given by mouth every morning.

4. Fluid should be limited to 1,000 cc. in the twenty-four hours with the most liberal possible supply of carbohydrate and vitamins.

5. Favor diuresis by caffeine with sodium benzoate 0.5 Gm. given intramuscularly every four hours as long as required. Digitalis and other cardiovascular stimulants may be given as indicated.

PSYCHOTHERAPY

If the delirium develops in a relatively nontoxic condition, one should study the patient's personality to prevent and ameliorate disturbing emotional factors. Many convalescences are prolonged when all traces of organic disease have gone and restorative processes should have been completed, simply because the patient has developed a neurasthenic syndrome precipitated by the physical illness and he is now activated by the disturbing emotions that were latent for a long period before the illness.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

DRIFLASH ELECTRO-SURGICAL UNIT ACCEPTABLE

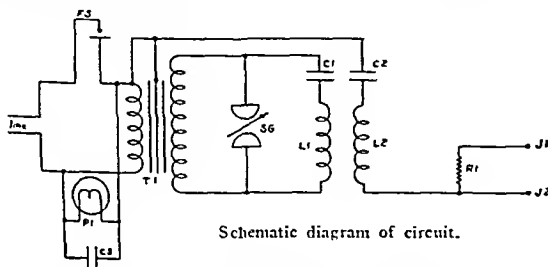

Manufacturer: General Automatic Corporation, Macedonia, Ohio.

The Model C-100 Driflash is a spark gap electrosurgical unit intended for desiccation and fulguration by the monopolar technique only. The unit is housed in a molded plastic case with a hanger so that it may be hung on the wall. A foot switch operates the unit, and a pilot light indicates when it is energized.

The following information was submitted by the firm: A high voltage transformer supplies 1,500 volts on an open circuit; the spark gap points are of tungsten; the coil assembly is wound on a fiber form; the condenser assembly is a copper mica assembly between aluminum castings. Two outlet jacks are provided. Both the condenser and the coil assembly are insulated for voltages at least five times higher than those actually encountered. The power output is approximately 10 watts.

Driflash Electro-Surgical Unit.

Schematic diagram of circuit.

In the advertising no therapeutic claims are made for the device other than that it is a suitable device for desiccation and fulguration. The Council's clinical investigation of the unit revealed that it gave satisfactory service.

Assuming that only treatment of small lesions of the skin is to be undertaken and that only monopolar technique is desired, the intensity of fulguration and desiccation is adequate for

practical purposes. The control whereby one can reduce the intensity from maximum power down to a point at which there is no effect seems quite even and satisfactory.

The Council on Physical Therapy voted to accept the Driflash for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. PAUL NICHOLAS LEECH, Secretary.

HAZARDS OF BROMIDISM IN PROPRIETARY AND UNCONTROLLED HYPNOTIC MEDICATION: NEUROSINE (Dios Chemical Company) NOT ACCEPTABLE FOR N. N. R.

Lately the medical profession has been deluged with pamphlets extolling the value of bromides over the barbitol preparations. These pamphlets have been sent out by the Dios Chemical Company, promoters of "Neurosine." An introductory paragraph of one of the pamphlets states:

In prescribing sedative medication, the physician is faced with the problem of selecting the most suitable, yet safe, agent. Shall he choose one of the barbiturates, which though they have a powerful, prompt hypnotic effect, are known to be dangerous and with distinct tendencies toward inducing tolerance and addiction? Or, shall he rather choose a milder sedative of certain action, with decades of safe, effective clinical application, such as a tested combination of bromides with therapeutic adjuvants (Neurosine)?

The author of the article is stated to be Dr. Frederic Damrau, who makes his services available to quite a number of proprietary concerns. In view of this, the Council calls the attention of the medical profession again to the hazards of bromidism in their indiscriminate use in hypnotic medication.

In the consideration of the use of any drug there are two aspects of its toxic action that must be considered: first, the acute toxicity and, second and often more important, the chronic toxicity. The acute toxicity can be readily gaged by determination of the acutely fatal dose in animals and comparison of this with the dose necessary to bring about the desired pharmacologic action, thus obtaining the therapeutic index. With due allowance for species differences, these results may be applied to the use of the drug in man. Chronic toxicity may be due to either or both of two characteristics: first, to slow progressive damage to some organ or its function, because of a long continued maintenance of a concentration of the drug that would not produce irreversible changes in a short time and, second, to slow excretion or destruction of the drug, with the resultant attainment of a very high level in the body after prolonged administration. The bromides fall into the latter category, and it is because of this factor that their indiscriminate use such as in proprietary sedatives has led to so many cases of chronic bromide intoxication.

BLOOD BROMIDE AND INTOXICATION

The use of bromides as depressants of the central nervous system dates back a century, and it was not long after their introduction that the first case of intoxication was reported by Huette¹ in 1850. There followed reports of individual cases from time to time, but it was not until Wuth² called attention to the syndrome in 1927 and described his modification of the methods of determination of blood bromide previously described by Walter and Hauptmann that the subject was given adequate attention, and reports of the incidence of chronic bromide intoxication were forthcoming. Wuth reported elevated blood bromide values in 21 per cent of 238 patients admitted to the Henry Phipps Psychiatric Clinic, of whom 8 per cent showed clinical evidence of bromide intoxication. Probably the largest series of cases was reported by Wagner

1. Kamman, G. R.: *Minnesota Med.* 21: 484 (July) 1938.
2. Wuth, Otto: *Rational Bromide Treatment*, J. A. M. A. 88: 2013 (June 25) 1927.

and Bunbury, who found 7.7 per cent of patients admitted to the Colorado Psychopathic Hospital to have blood bromide concentrations above 75 mg. per hundred cubic centimeters, with 4.4 per cent showing symptoms of bromide intoxication. Hanes and Yates³ found that more than 700 patients admitted to Duke Hospital had elevated blood bromide concentrations, of whom 400 had had concentrations above 50 mg. per hundred cubic centimeters over a period of six and one-half years, during which time they represented 0.9 per cent of total admissions. Of 500 dispensary patients, 5.8 per cent had blood bromide concentrations above 50 mg. It is the opinion of these authors that 5 per cent of admissions to institutions are due to bromide intoxication.

BEHAVIOR OF BROMIDE IN THE BODY

In order to understand the high incidence of intoxication with this drug, one must consider briefly its behavior in the body. The bromide ion is readily absorbed from the stomach and intestine, to such an extent that even after the ingestion of large amounts very little is found in the feces. The absorbed bromide is capable of displacing chloride from the tissues, the amount so displaced depending on the relative amounts of the two halides ingested. Thus either an increase in bromide or a decrease in chloride ingested results in a rise in the bromide concentration in the tissues. Normally, the chloride concentration is maintained within fairly narrow limits, the absorption being balanced by urinary excretion. Because bromide is excreted more slowly than chloride, even though the amount of bromide ingested is inferior to the amount of chloride, bromide will gradually replace chloride in the tissues. It is estimated that for every gram of bromide ingested from 10 to 15 Gm. of chloride should be taken and that with this ratio there is little danger of cumulative toxicity.⁴ Replacement of 40 per cent of tissue chloride by bromide is stated by Bernouilli⁵ to be fatal and 30 per cent definitely toxic.

FACTORS IN BROMIDE TOXICITY

Thus it is seen that a number of factors other than the absolute dose of bromide are concerned in the possible development of bromide intoxication. A reduction of chloride in the diet is effective in increasing blood bromide concentration on a constant bromide intake, while kidney damage, by interfering with bromide excretion, may have the same effect. Added to this is the generally accepted fact that the threshold of toxicity varies greatly from one individual to another, much as is the case with alcohol. It may be stated that any blood bromide concentration above 150 mg. per hundred cubic centimeters carries with it the possibility of bromide intoxication, although cases have been reported in which as high a concentration as 380 mg. per hundred cubic centimeters was tolerated without untoward symptoms.

FALSE SENSE OF SECURITY IN LOW ACUTE TOXICITY

Probably the very low acute toxicity of bromide is responsible more than any other factor for the high incidence of bromide intoxication. The knowledge that very large single doses may be taken without other effect than the desired sedation has led to a false sense of security on the part of layman and physician alike in the prescribing of bromides, the name of which has become a household word synonymous with mild sedation. Nor has this dangerous sense of security been decreased by the publication in the medical literature⁶ and in the advertisements of certain drug firms⁷ of data emphasizing the low acute toxicity of bromides, without adequate consideration of their cumulative action.

A striking example of the latter type of publication is a pamphlet circulated by the Dios Chemical Company of St. Louis, advertising their product "Neurosine" entitled "Do Sedatives Harm the Brain," under the authorship of Frederic Damrau, copyright 1939. Probably the most objectionable phase of the claims made in this publication lies not in the

virtues attributed to "Neurosine" but rather in the lack of appreciation of the cumulative effects of continued bromide medication. Certain of the statements made are worthy of comment. Great stress is laid on the lack of acute toxicity of bromide, the statement of Cushny being quoted that "acute fatal poisoning has seldom or never occurred in man." In contrast to this, the whole subject of cumulative toxicity is disposed of in a short paragraph, the definite impression being given that the incidence of such toxic effects is negligible and the treatment simple and rapidly effective, than which nothing could be less true. Damrau further states "The bromides are never habit forming," yet cases of addiction to "Bromo-Seltzer" have been reported. Importance is attributed to animal experimentation, autopsies of the experimental animals being claimed which "failed to show any pathological changes of the brain, heart, lungs, kidneys or spleen." Yet a careful perusal of this work shows that only acute experiments were performed in which no opportunity for cumulative action was present. Nevertheless, in the next paragraph the indications for the administration of "Neurosine" include such essentially chronic conditions as "neurasthenia, hysteria, menopause neuroses, alcoholism, the insomnia habit, and epilepsy." The applications of "Neurosine" seem endless, as a later paragraph gives unqualified commendation for its use in Sydenham's chorea, habit spasms and exophthalmic goiter, but in all these conditions more specific treatment is certainly indicated. Superiority over barbituric acid derivatives is claimed on presentation of fragments of evidence, mostly original with Damrau, without adequate presentation of the other side of the case. Finally, a plea is made that "Neurosine" be prescribed because it is "strictly an ethical preparation," a plea which loses something in sincerity when it is remembered that the Dios Chemical Company goes to considerable trouble and expense to see that the preparation is dispensed in the original bottle, which has both the name "Neurosine" and the name of the firm blown into the glass, thus affording the patient an excellent opportunity for continued self administration of a potentially dangerous drug.

Furthermore, the stress placed on the undesirable features of barbiturates is out of all proportion in Damrau's discussion of the action of bromides. Every physician will agree that there are undesirable side actions of the barbiturates which are well understood and documented, but it is quite inappropriate in a discussion of sedative drugs to single out this particular group for condemnation while minimizing, or even ignoring, more or at least equally glaring faults in other groups of drugs, especially the bromides. Although the obvious purpose of advertisements is to sell the product advertised, such an attempt based on part information and misinformation is misleading to the profession and the public and should be condemned.

The recent legislation aimed quite justifiably at the indiscriminate sale of the barbiturates has resulted in increasing the equally undesirable indiscriminate and unhindered sale of preparations containing bromide. That ignorance regarding the potential danger of prolonged administration of bromide without adequate supervision is not restricted to the layman is eloquently attested by the number of patients referred to psychiatrists by physicians who have themselves administered bromides to a point of chronic intoxication which they failed to recognize. Furthermore, Tod and Stalker⁸ report three physicians admitted to Maudsley Hospital for bromide intoxication due to self medication. Is it, then, any wonder that the layman, unaware of the potential danger of the drug, having as a matter of common knowledge the impression that bromides are "good for the nerves" and having the choice of any number of attractively dispensed proprietary preparations which he may purchase with no more restriction than is placed on the sale of cosmetics, all too frequently finds himself ultimately in a psychiatric institution? Surely the remedy does not lie merely in the printing of the composition of the product on the label, for so far as bromides are concerned this is rather an added inducement for the buyer, but rather in placing similar restrictions on the sale of these preparations as have

already been placed on the sale of the barbiturates. Finally, the education of the medical profession to the proper use and control of bromide medication is important.

PROPER CONTROL OF BROMIDE MEDICATION

Although there is some divergence of opinion as to the relative value of bromide in the treatment of epilepsy, since the advent of phenobarbital and dilantin sodium, the drug is undoubtedly effective in certain cases and probably deserves some usage in this condition. It is a useful adjunct to the therapeutic armamentarium also as a mild sedative in certain neuropsychiatric conditions. Nor need its use be unduly hazardous if its potentialities for cumulative toxicity are borne in mind and adequate precautions are taken. These precautions consist essentially in a control of the level of the bromide concentration of the blood, endeavoring to attain the desired therapeutic result with as low a concentration as possible, and absolutely avoiding concentrations higher than 125 to 150 mg. per hundred cubic centimeters. The determination of bromide concentration of the blood by the method described by Wuth⁹ is simple and rapid and the apparatus required is inexpensive. Therefore, it is not unreasonable to ask that, if the physician is not willing to undertake the slight effort and inconvenience required to follow the blood bromide concentration, he should eschew the prescription of the drug entirely and confine himself to such sedative drugs as have been proved to be relatively noncumulative. If bromides are prescribed, the pharmacist should be advised not to refill the prescription without an order to do so, thus avoiding the danger of the patient's continuing the medication without supervision. If these precautions are adhered to, there is no reason why therapeutic use of this sedative should result in bromide intoxication.

MANIFESTATIONS OF BROMIDE INTOXICATION

As to the manifestations of bromide poisoning, suffice it to say that any organic reaction type may be simulated. However, in the majority of cases there are the signs of a toxic delirium, with retardation of thought, slurred speech, ataxia, tremulousness of the hands and disturbances of attention and memory. Hallucinations may occur, but frank hallucinosis is uncommon. Paranoid delusions are not infrequently seen. The presence of a pustular acneform eruption may aid in the diagnosis but is more frequently absent than present. Indeed, there seems to be no relation between the threshold for the dermatologic and neurologic manifestations of bromide toxicity. A history of ingestion of bromides is frequently very difficult to obtain, so that determination of the blood bromide concentration is the most reliable diagnostic measure.

TREATMENT OF BROMIDE INTOXICATION

Treatment consists first and foremost of abrupt cessation of bromide intake, with substitution of other sedatives only when restlessness cannot be controlled by such physical therapeutic measures as packs and tubs. Fluid intake should be kept up, parenterally if necessary. Diuretics are ineffectual in expediting excretion by the kidneys; the amount which can be eliminated by the bowels does not justify the drastic use of cathartics. The administration of sodium chloride in dosage of from 6 to 12 Gm. daily is effective in more rapidly displacing the bromide from the tissues. However, it is said by Strecker and Ebaugh¹⁰ that the displacement may take place more rapidly than does elimination by the kidneys, with a resultant temporary rise in blood bromide concentration, and therefore these authors believe that this procedure should not be instituted too rapidly. This must be borne in mind in giving parenteral fluids. Since a liter of physiologic solution of sodium chloride contains 9 Gm. of sodium chloride, dextrose is probably preferable, while the blood bromide concentration remains very high. The fact that in the presence of a large amount of bromide in the tissues a considerable proportion of the gastric acidity is due to hydrobromic acid,¹¹ which normally is reabsorbed in the intestine, opens another avenue for the elimination of bromide. Toenhart¹¹ was successful in

removing 5 Gm. of bromide by repeated aspiration of the gastric contents over a period of six days from a patient with an initial blood bromide concentration of 300 mg. per hundred cubic centimeters, with clinical recovery in this period. This is a considerable improvement over the two or three week period necessary with salt therapy only. The application of the Wangenstein technic of continuous suction probably would be still more effective. It is difficult to conceive how the removal of but 5 Gm. of bromide from a patient with a blood bromide content of 300 mg. per hundred cubic centimeters would be clinically effective. There must have been approximately 21 Gm. of bromide in the blood alone, and since the tissues contain on an average about one third the concentration of the blood, almost 200 Gm. more in the rest of the body. Then the removal of 5 Gm. of bromide represented a reduction of but 4 per cent of the total bromide content of the body. Obviously, more knowledge of the distribution and excretion of bromide is necessary for a full evaluation of this mode of treatment.

SUMMARY

Bromide therapy should not be attempted without careful control of the dosage both of bromide and of salt, so that the blood bromide concentration is not allowed to rise above the 125 to 150 mg. per hundred cubic centimeter level, which is the maximum safe therapeutic concentration. Care should be taken that the patient is not allowed to continue bromide medication without supervision. Blood bromide determinations should be carried out on all patients manifesting evidence of symptoms of the organic reaction type, such as confusion or delirium, and appropriate therapeutic measures instituted if toxic concentrations of bromide are found.

The Council reaffirmed its action of many years ago declaring "Neurosine" unacceptable for inclusion in New and Non-official Remedies because it is a mixture containing bromides sold under a proprietary name with unwarranted therapeutic claims.

HEMOLYTIC STREPTOCOCCUS ANTITOXIN- GLOBULIN-LEDERLE-MODIFIED NOT ACCEPTABLE FOR N. N. R.

The Lederle Laboratories, Inc., presented this product for the Council's consideration as a combination of hemolytic streptococcus antitoxins of broad valence identified as scarlet fever streptococcus antitoxin and erysipelas streptococcus antitoxin. The product was proposed for use in the treatment of severe and toxic cases of beta-hemolytic streptococcus infections, alone or as combined treatment using sulfanilamide for puerperal fever, erysipelas, septic sore throat, cellulitis and streptococcal pneumonia.

In the Council's consideration of the material presented, especially the advertising, question was raised as to the specificity of toxins of various strains of streptococci. It was pointed out that this was a controversial problem and that, while the firm had presented credible data to indicate that the preparation is apparently a combination of scarlet fever streptococcus antitoxin and erysipelas streptococcus antitoxin, it had presented no clinical evidence that hemolytic streptococcus antitoxin will be of great value in any streptococcal infection except scarlet fever.

Various passages in the advertising submitted by the firm were criticized and recommended to be deleted on account of the foregoing. It appears unnecessary to specify these passages from the advertising in this report. The following comment by a Council member sums up this consideration:

It seems probable that when current work on the hemolytic streptococcus matures the biologic treatment of streptococcal disease will have to be considered in a somewhat new light. Meanwhile it seems unfortunate to discuss questions which are still in the experimental stage with such finality as is done in the Lederle booklet on Hemolytic Streptococcus Antitoxin.

In view of the objections raised and of the fact that Lederle Laboratories, Inc., has not presented adequate clinical evidence to substantiate its claims, the Council declared Hemolytic Streptococcus Antitoxin-Globulin-Lederle-Modified unacceptable for inclusion in New and Nonofficial Remedies.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - - CHICAGO, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - - Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, SEPTEMBER 14, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.

2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.

3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.

4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.

5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.

6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.

7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.

8. Expansion of public health and medical services consistent with the American system of democracy.

THE PHYSICIAN AND THE DRAFT

The selective service act—usually called the conscription bill—has passed the House of Representatives and the Senate and now goes to the Conference Committee for final decision on certain differences. No doubt by the end of the week this act will have been passed by both houses and will have been signed by the President. Immediately, no doubt, in the individual states some thousands of draft boards or exemption boards will be established, with each of which there will be associated a physician. Physicians are already being asked in many states to volunteer for service with these boards. It has been suggested that they will be willing to contribute their services now as so many thousands of them did in 1917-1918. At that time arrangements were made to pay on a per diem basis for the services of physicians only in counties where physicians could not be found to contribute the services. We have no record of any such counties.

The duty of the physician associated with the draft board is one of the utmost importance in relationship to securing a proper personnel for military service. On the physician rests the major part of the responsibility of deciding promptly whether claims for exemption on account of physical disability are just. Considering the fact that the physician associated with such a board is a resident in the district over which he has jurisdiction, the physician is not in an enviable position. He must hear the pleas not only of his friends and neighbors but also of his patients. To resist such importunities requires common honesty of purpose and a courage to do one's duty which is fundamental in the character of every good physician. No doubt he will be called on to detect malingering, perhaps to pass on certificates from family physicians and specialists certifying to disabilities which he will have to verify. The duties of physicians on these boards require not only honesty of purpose and courage to do right, even at the sacrifice of private practice, but also professional alertness to detect malingering and misrepresentation.

It has been rather generally understood that the physicians on the draft boards will make only a preliminary survey of the candidates who come before them. Those selected will then be sent to special examining boards, which will be later constituted by the Army Medical Department. On these physical examining boards will rest the final decision as to whether or not the young man is to go to camp. These boards will be located in centers of population, preferably near military posts or stations, and will include eleven medical officers and one dental officer. More complete information relative to the establishment, perquisites and duties of these boards will be published later.

In 1918, it will be remembered by many physicians, each draft board bore a relationship to a medical advisory board on which were placed the duties which now will be placed on the physical examining boards. It was found in 1918 that an average of 8.1 per cent of those examined were rejected for physical defects which were not picked up by the physical examiners of the local draft boards. This represented a total of 172,000 men between Feb. 10, 1916, and Oct. 31, 1918. These men were transported at government expense; in some instances they claimed aggravation of existing disabilities during travel from their homes to the military camps. The purpose of the new technic is to eliminate to a certain extent the number of men who are ordered into service and subsequently have to be rejected, and to eliminate as far as possible the responsibility of the government to individuals who will be without military value. Thus it is apparent that again a great burden and a great responsibility are to be placed on the physicians of our country.

American physicians have never failed in the past to meet such a call. The members of the Committee on Medical Preparedness, who have been authorized by

the House of Delegates to cooperate with government officials in securing physicians for required services, have promised with confidence that the medical profession is ready and willing to do its part.

BROMIDES IN MEDICINE

The use of bromides as sedatives has been known for almost a hundred years. Although the first case of intoxication was reported soon after the initiation of this therapy, many believed that the administration of bromides caused little, if any, more deleterious effects than those following the use of chlorides. More recently bromide intoxication has become so prevalent that there is no longer any question that the various bromide preparations possess distinctive effects, especially on the central nervous system. A recent report¹ published in *THE JOURNAL* plainly indicates the frequency with which undesirable effects result from bromide administration. Although the condition appears to be common, physicians may fail to recognize bromide intoxication. There may be, then, a much higher incidence of toxicity than is generally recorded. A frequent cause of intoxication is continued self medication by patients using prescriptions issued by physicians to alleviate the chronic suffering of the alcoholic addict or psychoneurotic individual. This should constitute an ample warning against any desire for casually prescribing a bromide preparation for headaches, insomnia, restlessness or so-called nervousness without cautioning patients about "follow-up" visits.

Pharmacologically the bromides have, among other factors, one important action: Intake of the slowly eliminated bromides results in the elimination of the more rapidly excreted chlorides from the body, which is a decisive factor in the production of intoxication. Sleep is induced by causing decreased interest and sensitivity to disturbing influences or stimuli. Since the sleep is often not deep or refreshing, the patient may awaken feeling unrefreshed and showing evidence of mental confusion which may persist for several hours after waking.

The blood bromide concentration can be simply and inexpensively determined. A bromide content of the blood even as low as 50 mg. per hundred cubic centimeters of blood may in some persons result in mild nervous manifestations. Continued use may cause a chronic manifestation of intoxication often called "bromism," a syndrome which may show cutaneous eruptions, disturbances of digestion, disturbances of sensation or mental upsets.

Because of lack of restrictions on "over the counter" sale of the bromides there has been in the past little difficulty in the public obtaining them. One precaution, due to the new Food, Drug and Cosmetic Law, provides that drug labeling must carry "adequate directions for use" and "adequate warnings." The following label has

been suggested as an example, to be suitable for preparations containing bromides sold. "over the counter" without a physician's prescription and which are considered to be so dangerous with careless use that they should be sold only on a doctor's prescription:

Warning: Frequent or continued use may lead to mental derangement, skin eruptions or other serious effects.

Do not take more than the dosage recommended.

Not to be taken by those suffering from kidney disease.

The Washington bureau has released information explaining the attitude of the Food and Drug Administration in connection with the dosage of bromides. It is the belief of the administration that bromides may be considered dangerous drugs under section 502 (j) of the act if an equivalent to 15 grains (1 Gm.) of sodium bromide is taken in a single dose or if the total daily dosage is equivalent to 30 grains (2 Gm.) with an interval of not less than three hours between single doses. These restrictions do not, of course, apply to prescriptions issued by physicians.

Elsewhere in *THE JOURNAL* is a report² of the Council on Pharmacy and Chemistry on the hazards of bromides, particularly in proprietary medicaments. Although the mortality from bromide intoxication is relatively low, probably less than 1 per cent, recovery from symptoms of poisoning may require from one to six weeks. The bromides have played an important part in therapeutics, especially in the management of epilepsy, but because of adverse effects neurologists have often questioned whether or not the harmful effects from the bromides might overshadow their good. In the latter part of 1938 a group of manufacturers' representatives met in Washington to discuss a common attitude toward certain analgesic and sedative drugs, the bromides being included. As a result of this meeting an organization was established to investigate certain properties and to review the existing literature. The group later implied that many existing impressions were based on false interpretations and that death or intoxication resulting from the use of bromides was so rare that great difficulty was found in estimating the accuracy of the records. These representatives of a group of manufacturers had, of course, a common interest in commercial preparations which included the bromides.

In the hands of the average physician, sodium or potassium bromide is a useful remedy. Competent physicians recognize their value and the side reactions, but the public must be forewarned against self medication induced either by refilling of prescriptions without the authority of the physician or by the use of the bromide-containing mixtures on the market represented by such compounds as the well known type of acetanilid-bromide effervescent mixtures.

Bromide intoxication does vary with the individual. One person may take rather large quantities of bromide

1. Gundry, L. P.: Bromide Intoxication. *J. A. M. A.* 113: 466 (Aug. 5) 1939.

2. Hazards of Bromidism in Proprietary and Uncontrolled Hypnotic Medication: Neurosine (Dios Chemical Company) Not Acceptable for N. N. R., this issue, p. 933.

over a period of time with relatively little accumulation in the blood stream while another person may take relatively small quantities over the same period with large accumulation. Continued intake of significant quantities of bromides over indefinite periods inevitably leads to accumulation of bromides in the blood stream. Individuals may therefore be afflicted with symptoms of bromide intoxication from frank bromide poisoning to the intangible symptoms of irritability, tendency to dizziness, confusedness and vagueness of thinking. Other symptoms which have been reported include inability to concentrate, loss of ambition and interest in work and surroundings, hallucinations, disorientation and suicidal or homicidal impulses. The latter symptoms are all a part of the bromide psychosis.

In this day, when the emotional strains are already impinging to an alarming extent on the consciousness of the public in general, it is high time that society protected itself against the use of those preparations which may contribute to an alarming increase in various forms of mental upsets or even insanity. There is no need for hysteria over the unwarranted use of preparations containing potentially dangerous ingredients, but there is need for restricted self medication. With the conscientious and combined efforts of physicians, pharmacists and pharmaceutical manufacturers, such an aim can easily be achieved.

Current Comment

SCIENTIFIC COLLABORATION

Up to the immediate past, as pointed out recently in a leading article¹ in *Nature*, scientific collaboration has not been confined to the so-called democracies but has embraced all civilized countries. By the intensification of totalitarian policy, international scientific cooperation has been adversely affected. Indeed on several occasions international conferences of both medical and general scientific nature have been postponed or canceled. This has had the effect of forcing men of science of free countries into closer collaboration, as exemplified by the inauguration in 1938 of the British and American Association Lecture, sponsored by the respective Associations for the Advancement of Science. The discussion also discloses the fact that recently a strong group of French scientific workers was inquiring into the possibility of publishing periodically in *Nature* articles contributed by French men of science in the French language—a suggestion which was apparently viewed favorably by the editors of that journal. The comprehensive scheme for collaboration by means of the centralization of scientific knowledge developed by a French group and established by the French government's Centre national de la recherche scientifique called a Service de documentation under the direction of Prof. Pierre Auger was also discussed. This service initiated the publication of an analytic bulletin containing titles or short abstracts of papers published in the

chief journals on chemistry, physics, applied chemistry, technical physics, biochemistry and some branches of biology. Extensive use was to be made of microfilms, and bibliographies of special subjects were to be made by assembling sections of microfilm. The preliminary aspects of the service were limited to France, Great Britain and the dominions and colonies. According to *Nature*, during its brief life it received valuable aid from the Science Library in London. At the time of writing the article the plight of this service was unknown.

GARBAGE DISPOSAL AND TRICHINOSIS

Trichinosis is probably a greater problem in the United States than in any other country in the world.¹ Until comparatively recently the relatively high incidence of trichinosis in various population groups of the United States was not commonly appreciated. That garbage-fed swine are especially important as sources of human trichinosis has been repeatedly emphasized.² Scraps of pork are commonly present in garbage and up to 5 per cent of these scraps, including trimmings and other discards from butcher shops, hotels, homes and elsewhere, have been reported to contain live trichinae. Years ago it was observed that garbage-fed hogs exhibited a high incidence of trichinae, whereas swine raised on pasture or fed on cooked meat and corn either were free from trichinae or exhibited a low incidence of trichinosis. Recent studies indicate that geographic areas in which many hogs are raised on garbage are the areas having the most clinical trichinosis.³ Inquiries addressed to health officers in 964 cities brought out that the hog-feeding method of garbage disposal is the most common method practiced in these municipalities, although, of course, other methods of disposal, including incineration, fill and cover, and reduction, are to a lesser extent also used.³ Large numbers of hogs fed on uncooked municipally collected garbage are marketed each year, and trichinous pork from these hogs, in cases in which the meat is packed in uninspected packing plants, may even be incorporated in products customarily eaten raw by the consumer. According to Wright the results of this survey indicate that American municipalities, either directly or indirectly, are probably the largest feeders of raw garbage to swine and, consequently, these communities would appear to be chiefly responsible for the dissemination of trichinosis. This serious indictment implies that the municipalities themselves are contributing to the ill health of their own citizens; as long as our cities and towns continue to contribute to the spread of trichinosis they will constitute a serious deterrent to the control of this disease. Since hogs fed on uncooked garbage probably represent the chief source of human trichinosis, a more rigorous control of garbage feeding should be established. This can be done through regulations which provide for the licensing and supervision of garbage feeding plants, and for the cooking of garbage for a period sufficient to destroy all trichinae.²

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PROGRESS OF MEDICAL PREPAREDNESS STUDY

The Second Fifty Per Cent

On September 6 the Committee on Medical Preparedness had received 93,437 schedules from physicians throughout the United States and its outlying territories. This number represents 52 per cent of the 179,796 schedules which were mailed to physicians in July.

The response of physicians in different states showed a wide variation, from 83.2 per cent in Nebraska and 85.8 per cent in the Canal Zone to 38.5 per cent in New Mexico and 0.08 per cent in the Philippine Islands. Thirty-eight states showed more than 50 per cent of questionnaires returned.

By Corps Areas the percentage of returns was, on August 30, as follows:

First Corps Area.—Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, Vermont: 13,567 schedules mailed; 6,958, or 51.3 per cent, returned.

Second Corps Area.—Delaware, New Jersey, New York: 33,355 schedules mailed; 17,653, or 52.9 per cent, returned.

Third Corps Area.—District of Columbia, Maryland, Pennsylvania, Virginia: 21,543 schedules mailed; 10,639, or 49.4 per cent, returned.

Fourth Corps Area.—Alabama, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee: 18,148 schedules mailed; 9,012, or 49.7 per cent, returned.

Fifth Corps Area.—Indiana, Kentucky, Ohio, West Virginia: 18,100 schedules mailed; 9,892, or 54.7 per cent, returned.

Sixth Corps Area.—Illinois, Michigan, Wisconsin: 22,176 schedules mailed; 11,561, or 52.1 per cent, returned.

Seventh Corps Area.—Arkansas, Iowa, Kansas, Minnesota, Missouri, Nebraska, North Dakota, South Dakota: 18,341 schedules mailed; 11,846, or 64.6 per cent, returned.

Eighth Corps Area.—Arizona, Colorado, New Mexico, Oklahoma, Texas: 12,270 schedules mailed; 5,911, or 48.2 per cent, returned.

Ninth Corps Area.—Alaska, California, Idaho, Montana, Nevada, Oregon, Utah, Washington, Wyoming: 17,495 schedules mailed; 9,385, or 53.6 per cent, returned.

Canal Zone.—134 schedules mailed; 115, or 85.8 per cent, returned.

Hawaii.—472 schedules mailed; 194, or 41.1 per cent, returned.

Philippine Islands.—3,695 schedules mailed; 3, or 0.08 per cent, returned.

Puerto Rico.—486 schedules mailed; 264, or 54.3 per cent, returned.

Virgin Islands.—14 schedules mailed; 4, or 28.6 per cent, returned.

Now that the vacation season is nearing its close, some physicians may be expected to return the schedules which have been awaiting their return.

Changes of address should be reported promptly to the Directory Department of the American Medical Association so that the Committee on Medical Preparedness can supply schedules to physicians who could not be reached on the first mailing.

The first 50 per cent of returns represents a prompt and willing response from the physicians in all parts of the nation. It is earnestly hoped that the second 50 per cent will respond without delay.

U. S. CIVIL SERVICE COMMISSION APPEALS FOR 600 CIVILIAN MEDICAL OFFICERS

In connection with the immediate authorized expansion of the Army, there is need for 600 civilian medical officers for temporary or part-time service. The duties assigned to them will be performed later by commissioned officers of the Army Medical Corps if and when such officers are called to active duty. Appointees will not receive commissions in the Army as a result of their temporary or part-time service. The United States Civil Service Commission has prepared a questionnaire and is seeking to ascertain names of physicians in the United States available for these positions and to secure acceptances from them. Applications must be on file with the commission's Washington office not later than October 1 if received from states east of Colorado and not later than October 4 if received from Colorado and states westward. The salaries for the positions concerned will be from \$3,800 to \$4,600 a year, subject to a retirement reduction of 3.5 per cent. The work is largely in the field of industrial medicine. Application blanks may be secured by addressing the United States Civil Service Commission, Washington, D. C., requesting form 2398a, August 1940, covering application for Civilian Medical Officers, Temporary and Part-Time Service.

PROPOSED STUDY OF WARTIME DISEASES

The American Red Cross and Harvard University announced, August 18, the proposed establishment of a 100 bed hospital in England for the study and treatment of communicable diseases under wartime conditions, according to the *New York Times*. Announcement was also made of the formation of a new Harvard public health unit for field and laboratory work in epidemiology in Great Britain. The hospital, to be known as the American Red Cross-Harvard Hospital, will be constructed and financed by the American Red Cross. Harvard will furnish the medical staff of the hospital and assume responsibility for the scientific work. The purpose of the joint undertaking in addition to fulfilling an urgent need in England will be to acquire valuable information both relating to the control of epidemics under unusual or wartime conditions and to the organization of temporary mobile hospitals under similar conditions.

The work of the Harvard unit already has begun with the arrival in London of Drs. John E. Gordon and John R. Mote, professor of and assistant in preventive medicine and epidemiology in the medical school, respectively. The Red Cross will furnish the structure and equipment of a temporary or hut type of hospital, to be fabricated in this country, transported to England and set up there on foundations provided by the British Ministry of Health. It will also furnish the nursing and nonprofessional members of the staff and certain supplies for its operation. The Harvard unit will fur-

nish the medical staff of the hospital, Dr. Gordon to serve as its director under appointment from the Red Cross as well as director of the Harvard unit.

The Red Cross will be responsible for the general management of the hospital. Dr. Gordon and the superintendent of the hospital, to be appointed by the Red Cross in consultation with Dr. Gordon, will report to the Red Cross on matters of general management. On scientific and clinical phases of the hospital work in addition to laboratory and field work of the Harvard unit, Dr. Gordon will be responsible to and report to Harvard University.

PHILADELPHIA'S PREPAREDNESS PLANS

The *Weekly Roster and Medical Digest*, official bulletin of the Philadelphia County Medical Society, has established a medical preparedness section for the information of its members on military matters. The society's committee on medical economics is at work on measures to safeguard the practice of physicians called to military service and to pay them part of the fees collected from their practice during their absence. The committee is also trying to arrange some method whereby physicians on their return from service will be restored to whatever teaching, hospital, governmental and industrial positions they held when called away.

A questionnaire similar to that distributed by the American Medical Association has been prepared by the society in order that the society may have in its own files information it may be called on to give to military authorities. The questionnaire is being mailed to nonmembers as well as members of the society.

The county society has also offered its services to the state director of selective service in the selection of medical members of local draft boards under the selective service law.

The subjects of coming lectures in the course on medical preparedness which the society is presenting, in addition to those previously announced will be:

October 3, Concentrations of Civilian Personnel for Military Service—Epidemiological Aspects, Contagious and Venereal Disease Problems.

October 10, Expected Psychiatric Problems in a Mobilization.

October 17, Tissue Reaction to Missiles of War—Ballistics, The Surgery of War as Contrasted with Industrial Surgery.

Dr. James B. Mason, co-chairman of the National Defense Committee and chairman of the speakers' bureau, made a radio talk, September 2, on "The Philadelphia Doctor and Medical Preparedness."

MEDICAL PILOTS

Medical Pilots, a group in which membership is available to all white male American citizens who are licensed practitioners of medicine and members of their local medical society, was organized in southern California in June. Officers include Drs. Phillip Ross Sutherland, Los Angeles, president; Bartlett C. Shackford, Long Beach, vice president, and Colby Hall, Los Angeles, secretary. An active member in the group must have an active private pilot's rating or a higher rating. Associate members must have a solo rating. At a meeting in the Hollywood Athletic Club, Hollywood, September 5, Ensign Moulton Taylor discussed aviation radio and flying instruments in general.

Organization Section

WHAT SHALL WE TEACH?

Fourth annual symposium sponsored by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association in cooperation with the A. M. A. Sections on Ophthalmology, Pediatrics, Laryngology, Otology and Rhinology, and Preventive and Industrial Medicine and Public Health, Tuesday, June 11, 1940, Hotel Roosevelt, New York.

I. H. GOLDBERGER, M.D., Assistant Director of Health Education, Board of Education, New York City, Presiding

DR. GOLDBERGER: The presence here today of about seven hundred teachers is due to the action of the Board of Superintendents, who granted these health specialists a half-day holiday for the purpose of participating in the proceedings of this symposium. It is hoped that the papers which we shall hear this afternoon and the discussion that will follow will help to contribute to the study, planning and improvement of school health programs and thus pave the way to progress in improving the health of children and of the communities in which they live.

I. THE BUREAU OF THE CENSUS REVEALS HEALTH PROBLEMS

HALBERT L. DUNN, M.D.
Chief, Division of Vital Statistics, Bureau of the Census,
U. S. Department of Commerce
WASHINGTON, D. C.

Recently the Bureau of the Census has begun to modernize its educational approaches to the public. A portion of its data deals with the facts of birth, death and population. To a lesser extent fertility data, marriage and divorce statistics, facts about criminals, judicial decisions, insanity and hospitals are also of interest to health departments. Yet these data have remained essentially unused by the majority of American people. Four years ago the Division of Vital Statistics of the Bureau of the Census began the serious study of adapting the materials under its jurisdiction to the needs of public health. In some instances we have played an active role in attempting to understand the other person's point of view rather than passively waiting for him to ask questions. In the campaigns for more complete birth registration we have studied the interests of entire communities. We have become acquainted whenever possible with the leaders of community organizations. We have then remodeled stereotyped talks on birth registration and recast them in the language of the persons who are members of organizations representing vital forces in local communities.

Thus two steps are being taken by the division in adapting material under its jurisdiction to the needs of public health: the adoption of a philosophy of service and the study of the interests of others.

A third step, of great value, is publication in "small packages." The ordinary person finds statistics peculiarly difficult to assimilate in anything but small packages. This consideration gave birth four and a half years ago to the "Vital Statistics—Special Report Series."

Many special projects are planned which will supplement public health needs, including:

1. Restoration of marriage and divorce statistics.
2. Extension of knowledge on mental and feeble-minded institutionalized patients.
3. Collection of facts concerning hospitals and other institutions where people die.
4. Computation of three year death rates.
5. Calculation of time trends for principal causes of deaths.
6. Special data and studies on fatal accidents.
7. A nationwide county by county test of the completeness of birth registration.

Mimeographed copies of complete papers and discussion will be sent gratis by the Bureau of Health Education to persons professionally interested in health education.

8. Studies on birth rates and infant mortality in terms of the social economic factors.

9. Special monographic studies on certain causes of death. Four page county summaries will consolidate all important facts and there will be approximately 3,000 such releases.

II. THE COLLEGE HEALTH SURVEY REVEALS CERTAIN NEEDS OF THE LOWER SCHOOLS

RUTH E. BOYNTON, M.D.

Director, Students' Health Service, University of Minnesota
MINNEAPOLIS

The effectiveness of a health education program is usually measured by either an increase in health knowledge or an improvement in health habits of individuals exposed to health education. It is extremely important for all in health work to work together on a program which will have continuity and progression.

The evaluation of health knowledge of college students may be done in two ways: (1) by attempting to discover by the use of so-called health knowledge tests how well informed they are in health matters and what attitudes toward health they have developed, and (2) by determining from physical examination and health history the health status of the individual.

Of the 4,545 new students at the University of Minnesota examined in the fall of 1938-1939, according to their health histories 98 per cent were thought to have an adequate diet and good eating habits. Ninety-three per cent obtained from seven and one-half to eight hours of sleep. Approximately 77 per cent of the men and 58 per cent of the women engaged in no extracurricular activities. About 15 per cent took no form of physical exercise. About 40 per cent had been immunized against diphtheria; 85 per cent had been successfully vaccinated against smallpox. Twenty-five per cent of the women and 9 per cent of the men were 10 per cent or more underweight; 17 per cent had an A posture and 21 per cent had a posture designated as C or worse. Sixty-seven per cent had moderate or excessive dental caries; 76 per cent had normal vision.

Results of health knowledge tests given university students are indications of the need for improved health teaching in the lower schools. They reflect the need for an extension and improvement in health teaching in all the schools.

Correct health knowledge is a first step toward better health practices. The desire to practice better health habits is the ingredient needed. Health instructors must find some way to develop an interest in better health habits.

Studies showing the lack of health knowledge of students should stimulate expansion in our health program and give encouragement to the providing of a continuous, well organized and progressive curriculum in health from kindergarten through college.

III. RELATIONSHIPS BETWEEN HEALTH EXAMINATION AND HEALTH EDUCATION

CHARLES C. WILSON, M.D.

Director of Physical and Health Education, Board of Education
HARTFORD, CONN.

Health education is not medical education; it is education which the layman needs to promote his own health and to cooperate in maintaining and promoting the health of his community. The health examination is one means of determining individual health needs or health problems. The recognition of unmet health needs should be followed by a planned program of education and guidance, initiated by the school medical adviser and continued by the teacher and school nurse. Acquaint the pupil and his parents with the significance of conditions found and the advantage of treatment. Personal health problems can be helped by educational efforts of teachers and nurses. These educational efforts relating to health needs, as revealed by health examinations, should aim to teach (1) the importance of preventive measures and of securing

attention for remediable defects and abnormalities, (2) the dangers and limitations of self diagnosis and self treatment, (3) where treatment is to be secured and (4) the necessity of each individual's assuming some responsibility for his own health care.

Health education should be related to life rather than be a learning of abstract words and ideas. Individual health guidance and group health instruction can be based, in part, on the problems revealed by health examinations.

Suitable facilities are a prerequisite for examinations which will have desirable educational results. Schools must provide attractive health guidance rooms permitting privacy during examinations and conferences. The health examination should be a pleasant experience and its educational outcome requires that a study be made of school health procedures. There should be opportunity for the physician to explain his observations and recommendations. With histories, with facilities for privacy and with adequate time the physician can conduct health education conferences rather than hurried, superficial inspections.

IV. THE INTERESTS OF CHILDREN VERSUS DICTA OF EXPERTS AS BASES FOR HEALTH INSTRUCTION

DOROTHY B. NYSWANDER, PH.D.

Director, School Health Study Committee
ASTORIA, N. Y.

Experts in the field of public health, private practice and education have succeeded in changing old attitudes toward health and in creating new attitudes as to how people should think and behave when confronted by health problems.

The health educator in the schools has recourse only to the experts who have said that certain facts were important and that undoubtedly teaching them must bring values in their wake. Thus the health educator leaves himself wide open to criticisms by educational psychologists who have for years been exploring not only what children need to learn in arithmetic, spelling and reading but how children learn these subjects. The teaching of health has been a stepchild of the classroom teacher. Without the results of research to guide her comparable to that for the three R's, she has had little help on what to teach or how to teach the facts, attitudes and habits involved in healthful living.

The beginning and end of the learning process is the child himself. Experts often fail to recognize this. Too often the expert thinks of what he wants to accomplish and forgets that it is the child who has to reach goals of his own choosing. Health educators must integrate the information needs and dynamic interests of the child through worth while life experiences.

Our courses of study in school health resemble too much the emphases which we are using in adult health education programs. They have been built around health or disease entities rather than around children's interests. Certain subjects may be of interest to the experts but do they have meaning or interest to children? For young children health is a series of specific knowledge and attitudes but these should be taught in connection with real projects of living and planning and thinking so that generalizations will emerge from these specific learning activities at a later period.

The sounder education becomes in its principles of teaching, the less costly may be the education of the adults in the community. And it is to the furthering of research in methods and technics of education in the schools that we now need to turn.

DISCUSSION

DR. RUTH M. BAKWIN, New York: Health examinations cannot be done *en masse*. The number of children per hour which most school physicians are expected to examine leaves the results meaningless. A health examination is the most difficult type of examination and the medical profession is not yet prepared to make a good health examination. Emphasis in the school should be on health education instead of on exam-

ination. Education is the instrument of a democracy, and with information available in this field better national health may be expected.

IRA V. HISCOCK, Sc.D., New Haven, Conn.: After decisions have been reached as to What to Teach and How to Teach, we need to consider how the process is to become dynamic and vital in a given community. The task may be embraced by giving emphasis to complexity, critical evaluation, clarity, content, concentration, curriculum, continuity, calendar, coordination, cooperation and cost.

REV. WILLIAM R. KELLY, New York: Inconsistency between knowledge and practice may be called the moral problem of health education. Our aim should be for a greater measure of consistency between health knowledge and practice on the part of pupils, teachers and all concerned with the health program.

DR. HARRY E. KLEINSCHMIDT, New York: We who undertake to teach must determine skilfully and precisely what should be taught and what may well be left out of the curriculum. What is the good of expert teaching technic if what we teach is pointless, unsound or incomplete? The most important thing to teach is that intangible something we call attitude. It is the scientific approach we are trying to cultivate. Out of a mass of technical knowledge we must select those particular elements which, if learned and assimilated, will lessen the drag of sickness and make life sweeter.

DR. GEORGE M. LYON, Huntington, W. Va.: Our health education plans must be simplified as much as possible. Controversial issues must be presented in a sensible manner and all the practices and teachings must be consistent with recognized possibilities and limitations; otherwise the school health education programs cannot be educationally sound or socially desirable.

DR. DEAN F. SMILEY, Ithaca, N. Y.: It is important that we give each child a systematic logical knowledge of his body so that when unexpected health problems arise in his after-school years he will have a sufficient number of scientific facts and principles in the back of his mind to make his problem solving easier and more nearly correct. I would argue, therefore, for both a student interest approach and a logical or systematic approach in health education.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status.—H. R. 10132, the Wadsworth conscription bill, has passed the House. Section 3 of the bill provides, in part, that in case of any person who during the year 1940 entered on attendance for the academic year 1940-1941 (1) at any college or university which grants a degree in arts or science, to pursue a course of instruction satisfactory completion of which is prescribed by such college or university as a prerequisite to either class of such degrees or (2) at any university described in 1 to pursue a course of instruction to the pursuit of which a degree in arts or science is prescribed by such university as a prerequisite, if, during his attendance at such college or university while pursuing such course of instruction, such person is selected for service and training prior to the end of such academic year, or prior to July 1, 1941, whichever occurs first, his induction into the land or naval forces shall, on his request, be deferred until the end of such academic year, but in no event later than July 1, 1941. During a discussion of this particular section on the floor of the House the question was raised as to whether or not the exemption in favor of students applied to those in attendance at medical schools. Representative May, Kentucky, who was in charge of the bill, answered the question in the affirmative.

Bill Introduced.—H. R. 10484, introduced by Representative McCormack, Massachusetts, provides that no individual who is licensed to practice medicine under the laws of any state, territory or the District of Columbia shall be ineligible for appointment, or for examination, as a medical officer in the active or reserve components of the military or naval forces of the United States solely by reason of any rating or classification of the medical school from which such individual was graduated.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Appointments to State Health Board.—Drs. Amos Christie and Charles E. Smith, San Francisco, have been appointed members of the state board of health. They succeed Drs. Howard Morrow and William R. P. Clark, both of San Francisco, who resigned when the headquarters of the board were moved from San Francisco to Los Angeles, it was reported.

Society News.—Dr. Arthur Carol McKenney Jr. discussed "Medical Aspects of Fundus Examination" before the San Francisco County Medical Society, September 10, and Drs. Samuel D. Aiken and George S. Campion gave a description of fundi with colored photographs. All are of San Francisco. —The Los Angeles County Medical Association will devote a general meeting, September 19, to a discussion on "The Medical and Religious Rights of the American Citizen Under Increasing Government Control." The speakers will include representatives of medicine and of different religious faiths.

DISTRICT OF COLUMBIA

Annual Scientific Assembly.—The Medical Society of the District of Columbia will hold its annual scientific assembly, October 15-17. The theme this year will be cardiovascular-renal disease.

The Kober Lecture.—John R. Mohler, D.V.M., chief of the bureau of animal industry, U. S. Department of Agriculture, Washington, has been chosen Kober lecturer for 1941 under the rules governing an endowment fund established by the late Dr. George M. Kober. Dr. Mohler will deliver the lecture, March 28, on "Undulant Fever," under the auspices of Georgetown University. Dr. Kober stipulated, among other things, that a lecturer, to whom an award would be given, was to be chosen every third year by an executive board representing the Washington Academy of Sciences, the National Tuberculosis Association, the Anthropological Society of Washington and the Medical Society of the District of Columbia. Dr. Mohler received his degree of doctor of veterinary medicine from the University of Pennsylvania in 1896. He has been awarded many honorary degrees, is a member of several scientific societies and was president of the American Veterinary Medical Association in 1913.

ILLINOIS

District Meeting.—The fall meeting of the Iowa and Illinois Central District Medical Association will be held at the Le Claire Hotel in Moline, September 18. The speakers will be Drs. Earl B. Ritchie, Davenport, Iowa, who will present "A Short Résumé on Industrial Dermatoses," and Percy S. Pelouze, Philadelphia, "Gonococcal Infections and Sulfonamide Compounds."

Personal.—Dr. Seymour Fisher, recently medical director of the Soldiers' and Sailors' Children's School Hospital, Normal, has been appointed superintendent of the division for handicapped children in the Illinois State Department of Public Welfare, Springfield. He succeeds Dr. Paul H. Harmon, now of Sayre, Pa., who resigned late in 1939. Dr. Sol Paul Dikowsky, Chicago, was appointed pediatrician at the Normal institution to succeed Dr. Fisher.

Schools Closed.—Poliomyelitis Suspected.—The elementary and high schools of the city of Virginia in Cass County have been closed for two weeks because five children in the community were ill with what was thought to be poliomyelitis, according to the Chicago Tribune, September 10. The report stated that the illness in three of the five children had been definitely diagnosed as infantile paralysis and that the other two were suspected cases.

INDIANA

Memorial Tablet to Pioneer Physicians.—A bronze tablet erected to the memory of pioneer physicians of Clay County was dedicated, July 28, with John G. Benson, D.D., Indianapolis, as the principal speaker. The tablet has been placed in the Clay County hospital, Brazil, by the county medical society.

Retiring Dean Honored.—The Monroe County Medical Society held a dinner meeting in honor of Dr. Burton D. Myers, July 10, to mark his retirement as dean of the Indiana University School of Medicine at Bloomington. Dr. Myers had been dean of the Bloomington school since 1927. He joined the faculty in 1903 as professor of anatomy, becoming assistant dean in 1920. He retired, July 1, having reached the university's retirement age of 70 years. At the dinner Dr. Myers was presented with a life membership in the Monroe County Medical Society and speakers included Dr. Karl R. Ruddell, Indianapolis, president, state medical association; Herman B. Wells, LL.D., president of Indiana University; William Lowe Bryan, L.H.D., president emeritus of Indiana University; Attorney George Henley and Mr. Thomas A. Hendricks, executive secretary of the state medical association.

Short Courses in Tuberculosis.—The Indiana Tuberculosis Association is offering short courses in tuberculosis to practicing physicians. An afternoon and evening will be devoted to each course, which covers recent progress in treatment. The following sanatoriums have been selected as teaching centers:

Indiana State Sanatorium, Rockville, September 24.
Boehne Tuberculosis Hospital, Evansville, October 8.
James O. Parhamore Hospital, Crown Point, October 10.
Smith-Esteb Memorial Hospital, Richmond, October 10.
Irene Byron Sanatorium, Fort Wayne, October 15.
Sunnyside Sanatorium, Indianapolis, October 16.
Healthwin Hospital, South Bend, October 22.
Hillcrest Tuberculosis Hospital, Vincennes, October 22.
"Silvercrest" Southern Indiana Tuberculosis Hospital, New Albany, October 23.
William Ross Sanatorium, LaFayette, November 12.

Further information may be obtained from the association at 1219 Security Trust Building, Indianapolis.

KANSAS

Changes in State Health Staff.—Dr. Richard F. Boyd, assistant director of child hygiene, state department of health, Topeka, has been appointed director of local health, a position left vacant since the death of Dr. Rolla B. Stafford. Dr. Paul R. Ensign, Sparta, Ga., has resigned as director of the child health demonstration in Hancock County to become assistant director of child hygiene succeeding Dr. Boyd.

Annual Registration Due Between July 1 and October 1.—Physicians licensed to practice medicine in Kansas are required to renew their licenses annually between July 1 and October 1 and to pay a fee of \$1 to the secretary of the board of medical registration and examination. The secretary must strike from the register of licensed physicians the names of all physicians who fail to pay their annual registration fees as required by law. Physicians whose names are so removed may be reinstated by paying the secretary \$5 and submitting to him satisfactory proof of moral fitness.

KENTUCKY

Institute on Psychiatry.—The second regional postgraduate institute of the American Psychiatric Association will be held at the Central State Hospital, Lakeland, September 23 to October 5, in cooperation with the division of hospitals and mental hygiene. The lecturers will include Drs. Oskar Diethelm and Severo E. Barrera, New York; Edward G. Billings and Franklin G. Ebaugh, Denver; Maurice Levine, Cincinnati; S. Spafford Ackerly, Louisville; Joseph G. Wilson and John D. Reichard, Lexington; Lawrence Kolb, U. S. Public Health Service, Washington, D. C.; and Lieuen M. Rogers, U. S. Public Health Service, Springfield, Mo. Dr. Ebaugh is chairman of the committee on psychiatry in medical education of the American Psychiatric Association, which is sponsoring the series of institutes. The first was held at the Agnews State Hospital, Agnew, Calif., in June.

Society News.—The Christian County Medical Society honored Dr. Austin Bell, Hopkinsville, who is president-elect of the Kentucky State Medical Association, at a meeting in Hopkinsville, July 16, attended by 200 physicians from western Kentucky. Speakers were Drs. Arthur T. McCormack, Louisville, secretary of the state association, and John H. Blackburn, Bowling Green.—Drs. Philip F. Barbour and John Keller Mack, Louisville, addressed the Graves County Medical Society, Mayfield, July 17, on diarrhea and tuberculosis, respectively.—At a meeting of the Nelson County Medical Society in Bardstown, August 8, the speakers were Drs. James Murray Kinsman, on "New Treatments of Pneumonia"; Maurice G. Buckles, "Bronchoscopy in Diagnosis and Treatment of Chest Diseases," and Harry S. Andrews, "Treatment of Diarrhea in Children." All are of Louisville.

LOUISIANA

Tri-State Medical Meeting.—The thirty-fifth annual meeting of the Tri-State Medical Society will be held at the Washington-Youree Hotel, Shreveport, September 25-26, with the Shreveport Medical Society acting as host. The speakers will include:

Dr. Horace W. Boggs, Shreveport, Sulfathiazole—Clinical Application and Toxicity.
Dr. Roy R. Kracke, Emory University, Ga., Toxic Effects of Drugs on the Blood.
Dr. Robert K. Womack, Longview, Texas, Dysuria in the Female.
Dr. Louis F. Knoepf, Shreveport, Problems Concerning Some of the Indications for Chest Surgery.
Dr. Ralph H. Riggs, Shreveport, Bronchoscopy in Pulmonary Disease.
Drs. James K. Howles and Charles B. Kennedy, New Orleans, Diagnosis and Treatment of the Common Skin Diseases.
Dr. George W. Parson, Texarkana, Ark., Interesting Cases of Tularemia.
Dr. Arthur Neal Owens, New Orleans, A Consideration of the Treatment of Burns.
Dr. Robert W. Cooper, Shreveport, Use of X-Ray Therapy in the Treatment of Gas Bacillus Infection.
Dr. Silas C. Fulmer, Little Rock, Ark., Diagnosis of Heart Disease.
Dr. Joseph B. Wharton Jr., El Dorado, Ark., Pontocaine in Spinal Anesthesia.
Dr. Marvin T. Green, Ruston, Nonmalignant Conditions of the Breast.
Dr. Charles S. Sentell, Minden, Management of Acute Abdominal Emergencies.
Dr. Homer E. Prince, Houston, Texas, Asthma—Practical Considerations.
Dr. John A. Hendrick Jr., Shreveport, Present Status of Transurethral Prostatic Resection.

Dr. William H. Browning, Shreveport, will deliver his presidential address Thursday afternoon. The Tri-State Society is composed of physicians of Texas, Arkansas and Louisiana.

MISSISSIPPI

New Health Units.—A health unit has been established in Tishomingo County with Dr. William R. Armstrong in charge and headquarters in Iuka. A district health unit comprising Jasper and Smith counties has been organized with offices at Raleigh and Bay Springs. The department is under the direction of Dr. William F. Bell, Bay Springs. Dr. Sidney J. Williams, Livingston, health officer of Sumter County in Alabama, has been appointed director of the Commonwealth Fund health unit in Pike County, effective August 1.

MISSOURI

Annual Clinical Conference.—The Kansas City Southwest Clinical Society will hold its eighteenth annual clinical conference, September 30 to October 3, in the Little Theatre of the Municipal Auditorium, Kansas City. Guest speakers will include:

Dr. Harvey B. Stone, Baltimore, Intestinal Obstruction.
Dr. Ira R. Sisk, Madison, Wis., Chronic Prostatitis.
Dr. John T. King, Baltimore, Relation Between Coronary Disease and Hypertension.
Dr. Roscoe R. Graham, Toronto, Principle of Decompression and Defunctioning in Diseases of the Colon.
Dr. Fred M. Drennan, Chicago, Diagnosis and Interpretation of Clinical Findings in Peptic Ulcer.
Dr. Quitman U. Newell, St. Louis, Radiation Therapy in Gynecology.
Dr. Thomas Fitz-Hugh Jr., Philadelphia, Interrelationship of Cholelithiasis and Coronary Artery Disease.
Dr. Elliott C. Culler, Boston, Management of Cerebral Trauma.
Dr. Leo H. Garland, San Francisco, Diagnosis and Treatment of Bronchogenic Carcinoma.
Dr. John Alexander, Ann Arbor, Mich., An Evaluation of Thoracoplasty and Extrapleural Pneumothorax in the Management of Cavernous Pulmonary Tuberculosis.
Dr. Willis C. Campbell, Memphis, Tenn., Ununited Fractures of the Neck of the Femur.
Dr. James S. McLester, Birmingham, Ala., The Part Played by the Vitamins in Human Metabolism.
Dr. James G. Carr, Chicago, Prognosis in Cardiac Disease.
Dr. Jesse Bedford Sheldine, Dallas, Texas, Rules to Follow in the Treatment of Urticaria.
Dr. Luther Emmett Holt Jr., Baltimore, Newer Points of View in the Pathogenesis and Treatment of Infantile Eczema.
Dr. Arthur M. Alden, St. Louis, Neck Infections of Dental Origin.
Dr. Charles A. Bahn, New Orleans, Nutritional Eye Diseases.
Dr. Clifford J. Barborika, Chicago, Management and Treatment of Obesity.

A panel discussion on the anemias will be held in the ballroom of the Hotel President Monday evening and one on the heart Tuesday evening.

NEBRASKA

Personal.—Dr. Leland C. Albertson, formerly assistant superintendent of the Hospital for the Tuberculous, Kearney, has been appointed medical director following the resignation of Dr. Lawrence T. Sidwell.—Dr. Frederick R. Whittlesey, associate professor of medicine at the University of West Virginia School of Medicine, Morgantown, has been appointed director of the dispensary and coordinator of clinics at the University of Nebraska College of Medicine, Omaha.

Annual Registration Due On or Before October 1.—Physicians licensed to practice medicine in Nebraska are required by law to register with the Department of Public Welfare annually on or before October 1 and to pay a fee of \$1. A license expires if the licensee fails to register, but within the thirty days next following its expiration it may be revived by the payment of the registration fee and a penalty of \$1. If that is not done, an order of revocation is issued and thereafter the revoked license can be reinstated only on the recommendation of the board of examiners in medicine and on the payment of the renewal fees and penalty then due.

NEW HAMPSHIRE

Pediatric Meeting.—The New Hampshire Pediatric Society held its summer meeting in Manchester, August 30. Drs. John F. McCreary, Boston, and Simon Stone, Manchester, discussed uses of vitamin A and therapy of muscular dystrophy with vitamin E, respectively. Drs. MacLean J. Gill and Ursula G. Sanders, Concord, were elected president and secretary, respectively.

NEW YORK

Septic Sore Throat Traced to Raw Milk.—An explosive outbreak of septic sore throat in the village of Waddington, St. Lawrence County, in July was traced to raw milk from one dairy, *Health News* reports. Thirty-five persons were affected. The milker at the dairy gave a history of tonsillitis shortly before the outbreak. Two cases of mastitis were found in the cows, though the disease did not appear to be caused by the streptococci which belong to the group commonly encountered in human infections.

New Regional Society.—The Western New York Surgical Association was organized at a meeting at the Niagara Falls Country Club, August 8. Officers elected included Drs. Henry N. Kenwell, Buffalo, president; Donald P. Ross, Niagara Falls, and Harold A. Blaisdell, Jamestown, vice presidents, and John A. Post, Buffalo, secretary. The association stated its purpose to be "the cultivation, promotion and diffusion of knowledge of the art and science of surgery in its various departments, to sponsor and maintain the highest standard of practice in Western New York, to hold professional and social meetings and to publish transactions."

New York City

Hospital News.—A new dispensary unit of the department of hospitals was dedicated on Welfare Island recently. It will be associated with City, Manhattan and Welfare hospitals, located on the island, and will replace two old dispensaries. —Dr. Robert K. Lambert has been appointed attending surgeon in charge of the ophthalmologic service of Montefiore Hospital for Chronic Diseases.

Award to Dr. Goldwater.—Dr. Sigismund S. Goldwater, commissioner of hospitals of New York, has been selected to receive the 1940 Award of Merit of the American Hospital Association at its annual meeting in Boston, September 16-20. Dr. Goldwater has been a leader in the hospital field for many years. He graduated from University and Bellevue Hospital Medical College in 1901 and was superintendent of Mount Sinai Hospital from 1903 to 1916 and director from 1917 to 1929. From 1914 to 1916 he was health commissioner of New York. Dr. Goldwater was president of the American Hospital Association in 1908 and of the American Conference on Hospital Service from 1924 to 1926. Recently he was elected president of the Associated Hospital Service of Greater New York.

Lillian Wald Dies.—Miss Lillian D. Wald, founder of the Henry Street Settlement and of the first nonsectarian public health nursing system in the world, died September 1 at her home in Westport, Conn., aged 73. She resigned in 1933 as head of the famous settlement which she established in a tenement room in 1893; in 1937 she gave up the presidency of the board of directors. Miss Wald was active in the fight against child labor and in campaigns for better housing, children's playgrounds, school nursing programs and numerous other welfare projects. She was awarded the gold medal of the National Institute of Social Sciences, the Rotary Club's medal and the Better Times medal for distinguished social service. She wrote "The House on Henry Street," published in 1915, and "Windows on Henry Street" in 1934. On her seventieth birthday, March 10, 1937, at a public gathering in New York she received a distinguished service certificate of the city of New York from Mayor LaGuardia and was congratulated by President Roosevelt, Governor Lehman and others.

NORTH CAROLINA

Head of Anatomy Department Appointed.—Wesley C. George, Ph.D., professor of histology and embryology at the University of North Carolina School of Medicine, Chapel Hill, has been appointed head of the department of anatomy at the school. He succeeds the late Dr. Charles S. Mangum. Dr. George graduated from the university in 1911 and after several years of teaching took his doctorate in 1917. After service during the World War he taught at the University of Georgia and the University of Tennessee before returning to North Carolina in 1920 as associate professor of histology and embryology. He became a full professor in 1924.

Society News.—Elmer V. McCollum, Ph.D., Baltimore, addressed the Buncombe County Medical Society, Asheville, September 3, on "Contributions of Medical Science to Medicine."—At a meeting of the Mecklenburg County Medical Society, Charlotte, September 3, the speakers were Drs. Thomas D. Sparrow, on "Rationale of the Treatment of Goiter"; Otho B. Ross, "X-Ray Treatment of the Thyroid," and William Marvin Scruggs, "Total Obliteration of the Thyroid in Heart Disease."—Dr. Angus M. McBryde, Durham, addressed a joint meeting of the Alamance-Caswell Counties medical and dental societies in Burlington, August 13, on "Problems in Pediatrics."

OHIO

District Meeting.—The annual meeting of the Fifth Council District of the Ohio State Medical Association was held in Ashtabula, September 11. Dr. John E. Rauschkolb discussed "Ohio Medical Service Plans and Enabling Act," and speakers on the scientific program were Drs. Glen Keith Folger on "Treatment of Dysmenorrhea"; William C. McCally, "Surgical Drainage"; Curtis F. Garvin, "Chemotherapy of Streptococcal Infections"; Harold Feil, "Treatment of the Acute Heart Attack," and Robert F. Parker, "Modern Treatment of Pneumonia." All are from Cleveland.

Activities of State Medical Board.—The State Medical Board of Ohio reports the following recent results of prosecution for violations of the medical practice act, among others:

M. N. Ellis, Columbus, an unlicensed naturopath, was found guilty of "advertising and practicing" and fined \$150 and costs.

C. J. Williams, Columbus, an unlicensed naturopath, pleaded guilty and was fined \$100 and costs.

Isadore Silverman, unlicensed practitioner of Cuyahoga County, fined \$25 and costs.

Frank A. Miller, Medina, fined \$25 and costs.

Spafford Williams, Cleveland, fined \$50 and costs.

Olive Martin, Columbus, unlicensed chiropractor, placed on probation.

C. M. Leo, Columbus, unlicensed practitioner, fined \$100 and costs.

A. J. Mintz, Dayton, illegal practitioner, fined \$50 and costs.

S. M. Langstaff, unlicensed chiropractor of Madison County, fined \$100 and costs.

H. R. Reaver, Cincinnati, unlicensed chiropractor, fined \$50 and costs.

W. C. DeBenedis, Cincinnati, unlicensed chiropractor, fined \$50 and costs.

James R. Monroe, Toledo, unlicensed osteopath, sentenced to one year in the workhouse. This sentence was suspended on condition that Monroe leave the state.

PENNSYLVANIA

District Meeting.—The annual meeting of the Second Council District of the Medical Society of the State of Pennsylvania was held in Quakertown, September 12, with the following speakers: Drs. Clay Ray Murray, New York, on "Diagnosis and Treatment of Fractures of the Wrist and Elbow"; Francis F. Borzell, Philadelphia, president-elect of the state society, "Is Professional Independence Essential to National Health?"; Charles-Francis Long, Philadelphia, chairman of the state society committee on industrial health, "The Present Status of Industrial Medicine in Pennsylvania" and Chauncey L. Palmer, Pittsburgh, chairman of the committee on public health legislation, "New Health Legislation and the Practicing Physician." Fifty year testimonials were presented to Drs. Martin J. Backenstoe, Emmaus; Clarence S. Kurtz, Malvern; George F. Potteiger, Hamburg, and James T. Taylor, Pomeroy.

Pittsburgh

Incidence of Cancer in Allegheny County.—The U. S. Public Health Service recently issued results of a study of cancer in Pittsburgh and Allegheny County, the third area to be studied in a sampling survey of the incidence of the disease in the United States. A total of 6,103 patients with cancer were reported as under medical care during the year 1937. More than 50 per cent of the cases were reported by only 0.3 per cent of the physicians and 16 per cent of the hospitals. About half the physicians and hospitals saw no cases of cancer during the year. Eighteen per cent of all the cases reported were in persons under 45 years of age.

Grant for Biochemistry.—The John and Mary R. Markle Foundation has made a grant of \$3,000 to the University of Pittsburgh in support of an investigation of the biochemistry of bone marrow with special reference to the development of red blood cells. Richard H. McCoy, Ph.D., recently a member of the staff of the Wistar Institute of Anatomy, Philadelphia, has been appointed research fellow to work on the project in association with Max O. Schultze, Ph.D., research fellow in chemistry on a Buhl Foundation grant. The work, which will be carried on under the direction of Charles G. King, Ph.D., professor of chemistry, represents an outgrowth of earlier studies on the biochemistry of copper.

TEXAS

Memorial to Dr. Rawlings.—A new \$20,000 health center building was presented to the city of El Paso, August 11, by Mr. and Mrs. Charles Stewart Mott, Flint, Mich., as a memorial to Mrs. Mott's father, the late Dr. Junius A. Rawlings, who practiced in El Paso for many years. Dr. Thomas J. McCamant, former health officer of El Paso, paid tribute to Dr. Rawlings; Mrs. Mott made the formal presentation and Mayor Anderson accepted the keys to the building. Other speakers were Drs. Lyman T. Cox, city and county health officer; Simeon H. Newman, president of the board of health, and Miss Refugio Carreon, public health nurse. Dr. Rawlings died in 1936.

Society News.—The Texas Hospital Association has changed the place of its annual meeting for 1941 from the Hotel Galvez, Galveston, to the Hotel Adolphus, Dallas. The meeting will be held from February 27 to March 1.—At a meeting of the Big Bend Medical Society in Marfa, August 13, the speakers included Drs. Preston Hunt, Texarkana, president of the Texas State Medical Association, on "The Relation of the Medical Profession to the Present Political Set-Up"; Leopold H. Reeves, Fort Worth, "The Romance of Southern Medicine"; and Neil D. Buie, Marlin, president-elect of the state association, "The American Medical Association Platform."—Dr. Harris Hosen, Port Arthur, addressed the Jefferson County Medical Society, Port Arthur, August 12, on "Therapy in Respiratory Allergy."—Dr. Curtice Rosser, Dallas, addressed the Lamar County Medical Society, Paris, July 11, on "Management of Common Rectal Diseases."

WISCONSIN

New Milwaukee Health Officials.—Dr. Edward R. Krumbiegel, director of the bureaus of contagious diseases and school hygiene in the Milwaukee department of health since 1936, has been appointed health commissioner to succeed Dr. John P. Koehler, who resigned to seek the Republican nomination for United States Senator. Dr. Krumbiegel graduated from Marquette University School of Medicine in 1935. Dr. Errol V. Brumbaugh, deputy health commissioner for many years, retired to private life, August 15. Dr. Gerald F. Burgardt, Milwaukee, succeeded Dr. Brumbaugh.

District Meetings.—Speakers at a recent meeting of the Sixth Councilor District of the State Medical Society of Wisconsin in Fond du Lac were Dr. James Howard Johnson, Milwaukee, on "Fractures of the Hand" and the following from Chicago: Drs. Herbert E. Schmitz on "Carcinoma of the Cervix"; George O'Brien, "Coronary Heart Disease"; Jacob P. Greenhill, "Endocrinology in Obstetrics and Gynecology," and Charles Marshall Davison, "Acute Disease of the Abdomen."—At a meeting of the Ninth Councilor District in Marshfield, July 11, the guest speakers were Drs. Walter C. Alvarez, Rochester, Minn., and Walter M. Kearns, Milwaukee, on problems in gastro-enterology and urology, respectively.—Speakers before the Fifth Councilor District in Manitowoc recently were Drs. Doris F. Hopkins, Chicago, on "Allergy in General Medicine"; Raymond J. Jackman, Rochester, Minn., "Anorectal Disease"; Richard C. Adams, Rochester, "Anesthesia in Proctology," and Elmer L. Sevringhaus, Madison, on "Office Management of Diabetes." At an evening banquet Drs. Raymond G. Arveson, Frederic, president of the state society, and Eben J. Carey, Milwaukee, made addresses.

WYOMING

State Medical Election.—Dr. Roscoe H. Reeve, Casper, was named president-elect of the Wyoming State Medical Society at the annual meeting at Sheridan, August 11-13, and Dr. Peter M. Schunk, Sheridan, became president. Dr. Donald G. MacLeod, Jackson, was elected vice president and Drs. Marshall C. Keith and Frederick L. Beck, both of Cheyenne, were reelected secretary and treasurer, respectively.

PUERTO RICO

Inter-American Institute for Hospital Administrators.—Plans for an Inter-American Institute for Hospital Administrators to be held in San Juan, December 1-14, have been announced. The institute will be sponsored by the American College of Hospital Administrators, the University of Puerto Rico, the School of Tropical Medicine, the Puerto Rico Medical Association, the Puerto Rico Health Department, the Hospital Council of Puerto Rico and the Territorial Charity Board of Puerto Rico. It is planned to have lectures and discussions at the morning sessions, demonstrations in the hospitals in the afternoons and round table conferences in the evenings. Members of the executive committee, all of San Juan, are:

Juan B. Soto, Ph.D., chancellor of the University of Puerto Rico, San Juan, president of the committee.
Dr. Eduardo Garrido Morales, San Juan, commissioner of health of Puerto Rico.

George W. Bachman, Ph.D., director of the School of Tropical Medicine, San Juan.

Dr. Oscar Costa Mandry, San Juan, president, Puerto Rico Medical Association.

Dr. Leopoldo Figueroa, San Juan, president of the Territorial Charity Board.

Dr. Ramón M. Suárez, San Juan, president of the Board of Medical Examiners.

Mr. Felix Lamela, San Juan, president of the Puerto Rico Hospital Council.

Dr. Ramón H. Señeriz, acting director of the Bayamón District Hospital, Bayamón.

Mr. Robert Boyd, administrator of the Presbyterian Hospital, San Juan.

Information about the institute may be obtained from Mr. Lamela, executive secretary of the School of Tropical Medicine, San Juan, or from Mr. Gerhard Hartman, American College of Hospital Administrators, 18 East Division Street, Chicago.

GENERAL

Meeting of Railway Surgeons.—The fifty-first annual meeting of the American Association of Railway Surgeons will be held at the Palmer House, Chicago, September 16-18, under the presidency of Dr. Leonard A. Ensninger, Indianapolis. Among the speakers will be:

Dr. John Albert Key, St. Louis, Local Use of Sulfanilamide in Compound Fractures and Other Wounds.

Dr. Michael L. Mason, Chicago, Plastic Surgery and Repair.

Dr. Casper F. Hegner, Denver, Chest Injuries.

Drs. Sidney O. Levinson, Frank E. Rubovits Jr. and Heinrich Necheles, Chicago, The Clinical and Physiologic Aspects of Human Serum Transfusions.

Dr. Joseph F. Prinzing, Denver, Hernia.

Drs. Edward A. Oliver, Chicago, Louis Schwartz and Leon H. Warren, U. S. Public Health Service, Occupational Leukoderma.

Dr. John D. Shingle, Cheyenne, Wyo., Tick Fevers.

Dr. Newell C. Gilbert, Chicago, Reflex Causes for Angular Pain.

Dr. Andrew C. Ivy, Chicago, Recent Developments in Gastric Physiology.

Dr. Harold N. Segall, Montreal, Canada, The Aging Process.

At the annual banquet Tuesday evening, September 17, the guest speaker will be Mr. William Martin Jeffers, president of the Union Pacific Railroad, Omaha, on "The Importance of a Medical Department in Industry."

Academy of Ophthalmology and Otolaryngology.—The forty-fifth annual meeting of the American Academy of Ophthalmology and Otolaryngology will be held in Cleveland, October 6-10, with headquarters at the Hotel Cleveland and under the presidency of Dr. Frank E. Brawley, Chicago. The meeting will open with a general session Monday morning and mornings thereafter will be devoted to instructional courses. Scientific meetings of the sections on ophthalmology and otolaryngology will be held on alternate afternoons. Speakers at the opening session will be Drs. Brawley, who will deliver his presidential address; Secord H. Large, Cleveland, guest of honor at the meeting; Elmer L. Sevringhaus, Madison, Wis., on endocrinology, and Jacques J. Bronfenbrenner, Ph.D., St. Louis, on allergy. Among other speakers will be:

Dr. Walter B. Hoover, Boston, Progressive Gangrenous Ulcers of the Nose.

Dr. Frank R. Spencer, Boulder, Colo., Research Report: The Effect of Chemotherapy upon the Tubercle Bacillus with Special Reference to Sulfapyridine.

Dr. Hedwig S. Kuhn, Hammond, Ind., An Appraisal of Visual Defects in Industry.

Drs. Francis Bruce Fraley and Max M. Peet, Ann Arbor, Mich., The Fundi in Hypertensive Disease Before and After Splenectomy.

Dr. Joseph D. Kelly, New York, Operative Treatment of Bilateral Abductor Paralysis.

Drs. Chevalier Jackson and Chevalier L. Jackson, Philadelphia, Cancer of the Larynx—Its Increasing Incidence.

Dr. James W. Cheney, Wichita, Kan., Neoplasmod Treatment of Tracheoma.

Drs. Alkermor R. Reese and Hayes L. Martin, New York, The Treatment of Retinoblastoma by Radiation.

Immediately following this meeting, the first Pan American Congress of Ophthalmology will be held, October 11-12, under the auspices of the academy.

CANADA

Public Health and Medical Meetings.—The twenty-ninth annual meeting of the Canadian Public Health Association will be held in Winnipeg, September 19-21, in conjunction with the annual meeting of the Manitoba Medical Association. The two associations will hold two joint sessions and a joint luncheon and dinner. At the first joint session there will be a preliminary report of a survey of maternal mortality made in Manitoba by the department of health and public welfare, the medical association, the department of pensions and national health and the Rockefeller Foundation. Dr. John A. Ferrell, associate director of the International Health Division of the Rockefeller Foundation, New York, will be chairman of this session. At other sessions speakers will include Drs. John G. Cunningham, Toronto, on industrial hygiene and national defense; Claude E. Dolman, Vancouver, B. C., present status of milk-borne disease hazards, and J. S. Fulton, D.V.S., Saskatoon, Sask., contagious abortion of cattle and undulant fever in man. At a public meeting Dr. Harold W. Wookey, Toronto, will speak on cancer control and Dr. Donald H. Williams, Vancouver, recent progress in control of venereal disease.

CORRECTIONS

Argentine Memorial Day.—In the letter from Buenos Aires published in THE JOURNAL, July 27, page 314, in the last sentence, "Uruguayan memorial day" should have been "Argentine memorial day."

Yellow Fever on Ship from South America.—A news item was published in THE JOURNAL, August 24, under the heading "Yellow Fever on Ship from South America." It was reported that five cases of yellow fever were found on a British ship that had touched at Freetown, West Africa, but the item as published omitted mentioning that the ship started from Buenos Aires, Argentina. According to information received from Dr. Hugh S. Cumming, Washington, D. C., director of the Pan American Sanitary Bureau, the nature of the disease in these cases is still under investigation, the diagnosis being clinical only to date (September 4).

Government Services

Marine Hospital Enlarged

An addition to the U. S. Marine Hospital at Stapleton, N. Y., providing 305 more beds and other facilities was recently opened and occupied. The cost of construction was more than \$1,100,000, according to *Public Health Reports*. The addition brings the capacity of the hospital to more than 1,000 beds. It provides medical, surgical, psychiatric and other special care annually to more than 50,000 legal beneficiaries, it was said.

Mental Hygiene Consultation Service

The U. S. Public Health Service has established a new office, that of mental hygiene consultant to the states, for the purpose of encouraging and giving aid in the organization of state mental hygiene programs, with Passed Assistant Surgeon Victor H. Vogel in charge. Mental health projects will be recognized as approved objects for expenditure of Title VI Social Security funds allocated to state health departments for the extension of public health work.

Specialist in Tuberculosis Control for Indian Service

Dr. Horace De Lien, special physician in tuberculosis control, has been assigned to duty in the office of the district medical director, U. S. Indian Service, San Francisco, to assume direction of tuberculosis control activities among the Indian population of California. Dr. Lien has recently completed one year of educational experience at the Henry Phipps Institute of Philadelphia, previous to which he was in charge of the Indian Service Sanatorium at Fort Bidwell, Calif., now discontinued. Dr. Lien's activities will be extended to include tuberculosis control among Indians in Nevada and Utah in the near future. A recent x-ray survey of about 1,200 Mission Indians in Southern California revealed that about 1 per cent had significant tuberculosis, exclusive of primary lesions. In comparison with other groups of California Indians, this indicates a relatively low incidence of tuberculosis.

Compulsory Service of Physicians

The government is taking measures to ensure that hospitals and other medical services shall be adequately staffed with physicians. The Emergency Powers Act gives power to direct physicians to perform such services as may be specified. For the present the application of the act will be confined to physicians within two years of becoming qualified. This power will be exercised by the senior officers of the Ministry of Health, in which they will be advised by the central medical war committees of England and Wales and of Scotland. These committees already advise on the medical recruitment of the armed forces.

Medical Students and the War

The medical profession has been profoundly affected by the war. The younger physicians have been conscripted for military and naval service and most of the older ones are engaged in national service, such as examination of recruits for the fighting services, staffing of hospitals and first aid for civilian casualties from air raids. The life of the medical student is also greatly affected, though the authorities want to interfere with his studies as little as possible. The great hospitals in the cities have been converted into casualty clearing stations for the large numbers of wounded expected from air raids, which so far have not materialized, and the normal work of these hospitals has, as far as possible, been shifted to hospitals in safer areas in the surrounding country. This has meant a great disruption of teaching. Other effects are illustrated by the following:

More than 300 students of Leeds University Medical School will give up their long vacation to join a scheme of voluntary civil defense, which is designed to interfere as little as possible with their studies. The students are divided into three groups. The first group consists of sixty students due to take their final examination soon. They will serve in Leeds hospitals should air raids become severe. In the second group are 150 who have done at least six months of clinical work and not more than two and one-half years of hospital work. They are allocated to staffs of hospitals and are being trained to act as assistants to surgeons and anesthetists and as stretcher bearers while continuing their own work. The third group consists of 100 who have done less than six months of clinical work and more than two terms of anatomy and physiology. They are receiving an intensive course in first aid training and antgas work, and it is proposed to use them as mobile first aid squads.

The Physical Education of Youth

The war has increased attention to nutrition and physical training. In a debate in the House of Lords on the physical training of youth Lord Dawson said that good nutrition and physical education must go hand in hand. Fortunately in this country nutrition was going steadily forward. One of the cheapest campaigns which the Board of Education could institute would be to send vans to the rural districts where people could be shown how to choose and cook food. Physical education had been neglected because of the fallacy that education was necessary for the mind but not for the body. Our educators had not even been aroused by what had been going on in Germany in the last twenty years. But a good side of the picture was the progressive introduction of physical training into schools and the result was seen in a great improvement in physique. However, for most children physical training stopped at 14, the most critical age. The vital adolescent years were left to drift and the quality of the body to deteriorate. That

character did not deteriorate was remarkable. On the other hand, the Germans dealt thoroughly with the period of adolescence. At the very time when the influence of urbanization, mechanization and hustle needed counteracting by the building of individuals with bodies and minds self made, not machine made, we were without the means of training. In this crisis of our history the strength and endurance of our man power, including that of our youth, was vital. A director of physical education, with a small staff, should be appointed with even compulsory powers to direct physical education from the age of 14 upward. His work should be through existing organizations as far as possible. At 18 the training would be based on the War Office. Those in training would require supplementary nutrition. Milk was the solution of that.

Replying for the government, Viscount Clifden said that it was difficult to see how any compulsory scheme of training, even if desirable, could work effectively. It would lead to misrepresentation and might jeopardize general acceptance of more comprehensive training. Three factors were increasing the opportunities for young people to get regular training and recreation: 1. The Ministry of Labor and Board of Education are for the first time to be brought into direct contact with the large numbers of girls and boys in factories not now associated with any youth organization. It would be possible to make a direct appeal to them and provide adequate facilities. 2. All large voluntary organizations had agreed as a special wartime emergency measure to open their doors to all comers. 3. The Central Council of Recreative Physical Training and the football association had launched a scheme for training men and boys from 16 upward.

Homes in Australia and Canada for Physicians' Children

Schemes for the transporting of British children to the dominions, where they will be free from the war dangers which threaten the civilian population, are being pushed forward; but transport offers difficulties. Because of the possibilities of attacks by submarines, convoy is considered necessary and at the present moment the government cannot spare this. A special scheme for physicians' children is being arranged. Australian physicians have offered to take into their homes British physicians' children under the age of 16, either accompanied or unaccompanied by their mothers, to a total of 500. The arrangements will be made between the secretary of the British Medical Association and the secretary of the federal council of the British Medical Association in Australia. Parents will be responsible for the passage money and education, and maintenance will be the subject of individual arrangements. Physicians in Canada have offered to open their homes to 1,100 unaccompanied children of British physicians evacuated by the government and selected by the Children's Overseas Reception Board.

BUENOS AIRES

Aug. 9, 1940.

Psychoses in Relation to Language Isolation

Dr. E. Eduardo Krapf, director of a division in a large hospital for mental diseases in Buenos Aires, the Hospicio de las Mercedes, reported to the society for neurology and psychiatry a study of mental disorders in immigrants attributable to their ignorance of the native language. Fifteen years previously A. Ameghini had called attention in Buenos Aires to the fact that, while two thirds of the population of the country consisted of native stock, two thirds of the inmates of institutions for mental diseases were recruited from immigrant stock. His observations were confirmed and the same condition has been found in some other states. Spencer L. Dawes records similar observations (*Am. J. Psychiat.* 4:449 [Jan.] 1925) for the state of New York. Statistics such as these need to be cautiously

evaluated, since differences of age level must be taken into account. Immigrants represent largely the higher age levels in which the incidence of mental diseases is likely to be greater. Besides, immigrants are apt more frequently than natives to be without families and homes and hence more apt to be consigned to an institution. Other factors involve brooding over expatriation and nostalgia. Heredity and constitutional factors are also involved. Emigration from one's native land may itself be a sign of disturbed mentality or the social consequence of pre-morbid conditions or of unsteady character. Economic difficulties, hunger and wretchedness may also have pathogenic significance, tending to weaken the will to live. Temporary inability to adapt oneself to new climatic conditions frequently exercises a damaging effect. Krapf had stressed, in a previous article, the meaning of "shock," involved in the difference of seasons for the northern and southern hemisphere. The time during which adjustment to new atmospheric conditions had to be made represented a dangerous period of increased psychophysical lability and was indicated by depression in immigrant women. Usually complete and permanent recovery occurred after a few months. Disturbances arising from difficulties of adjusting oneself mentally to the national and social environment in a new country also play their part. Isolation and the feeling of loneliness may induce mental upsets either directly or concomitantly. It may be assumed that the psychologic relations between nostalgia and mental disorders are rooted primarily in a sense of loneliness. Psychoses due to the failure of adapting oneself mentally occur among all categories of immigrants, but they are peculiarly and with greater frequency observable, in Argentina, among immigrants of non-Latin stock, owing to their ignorance of the language of the country. This condition is similar to certain mental reactions observed in the deaf. Immigrants lacking the knowledge of Spanish lack an important means of social intercourse. In his study of the inmates of the Hospicio de las Mercedes, Krapf found in 1937 that among 215 inmates of non-Latin origin seventy-two (33.5 per cent) showed paranoic psychoses of all types, whereas only forty-two (19.5 per cent) of the inmates of Spanish descent were so affected. These observations agree with data gathered in New York by Benjamin Malzberg (*Psychiat. Quart.* 10:127 [Jan.] 1936) in which forms of paranoia predominated in persons of Latin stock, clearly a sign of the effect of mental isolation due to ignorance of the language spoken in the country.

Marriages

JOHN B. LARSON, Laurens, Iowa, to Miss Elizabeth Shortridge of Sioux Falls, S. D., in Remsen, Iowa, July 15.

LINCOLN BRUCE DONALDSON, Evanston, Ill., to Miss Gertrude Hagar Galloway at Hubbard Woods, June 29.

PRESTON DE WITT CONGER, Tifton, Ga., to Miss Mary Nell Morgan in Lakeland, Fla., June 23.

WILLIAM GEORGE MEYER, New York, to Miss Helen Hensel O'Hara of Dayton, Ohio, in June.

EUGENE A. SULLIVAN, Amboy, Ill., to Miss Alice Florence Crandall of Des Plaines, June 29.

RAVIS AARON BRANNON JR. to Miss Elizabeth Virginia Hudson, both of Utica, Miss., June 23.

FREDERICK TAYLOR MERCHANT, Marion, Ohio, to Miss Ethyl Rush of Columbus, Ind., in June.

FRANKLIN G. RUDOLPH, Hammond, Ind., to Miss Alene Bowman at Odon, Ind., August 3.

ROBERT LYMAN NELSON to Miss Phyllis Shaw, both of Duluth, Minn., June 1.

ALBERT L. MARSHALL JR., Indianapolis, to Miss Mary Cox of Odon, Ind., July 27.

FRANCIS DRAKE KENDALL, Columbia, S. C., to Miss Lella Lindler in June.

Deaths

Hans Zinsser ☉ Boston, eminent as a scientist, physician and author, died in New York, September 3, of leukemia at the age of 61. Dr. Zinsser had just published his autobiography under the title "As I Remember Him," and in this book he had forecast his death (*THE JOURNAL*, August 10, p. 481).

Hans Zinsser was born in New York in 1878. He received his A.B. degree from Columbia University in 1899 and his A.M. degree in 1903, and the honorary degree of D.Sc. was conferred on him by Columbia in 1929. After his graduation in medicine in 1903, he served an internship from 1903 to 1905 and then began his career as bacteriologist at the Roosevelt Hospital and the College of Physicians and Surgeons. For five years he served as instructor in bacteriology and hygiene in this institution and was also assistant pathologist in St. Luke's Hospital. He then became assistant professor and later professor of bacteriology at Stanford University. In 1913 he returned to Columbia as professor of bacteriology and remained until 1923, at which time he joined the staff of Harvard Medical School as professor of bacteriology and immunology, a position which he occupied until his death. He was consulting bacteriologist to the Children's Hospital and the Peter Bent Brigham Hospital. During World War I he served as major in the United States Army Medical Corps and later was promoted to the rank of colonel. He was sanitary inspector of the First Army Corps and of the Second Field Army of the A. E. F. in France and also was assistant director of laboratories and infectious diseases for the Expeditionary Force. In the summer of 1923 he went to Russia for the League of Nations Health Section as sanitary commissioner. In 1935 he was exchange professor in Paris and in 1938 at Peiping Union Medical College. For his work he was awarded the Distinguished Service Medal of the United States government, the Legion of Honor of the French government and the Order of St. Sava of the Serbian government.

Dr. Hans Zinsser was widely recognized as an authority in his field and held memberships in the National Academy of Science, the American Philosophical Society, the American Association for the Advancement of Science, the American Academy of Arts and Sciences, the Harvey Society, the Society for Experimental Biology and Medicine, the Association of Pathologists and Bacteriologists, the Society of American Bacteriologists, the American Association for Cancer Research, and the American Society for Experimental Pathology, also the American Academy of Tropical Medicine, the American Association of Immunologists, the American Public Health Association, the Association of American Physicians, the American Birth Control League, the American Committee for the Control of Rheumatism, the American Epidemiological Society and other organizations. He had been honored by election to membership in the Alpha Omega Alpha and Sigma Xi. Honorary degrees were awarded not only by Columbia but also by Western Reserve, Lehigh, Yale and Harvard.

Dr. Hans Zinsser began his writing first as a contributor of innumerable periodical articles to medical science, his books including the *Textbook of Bacteriology*, 1911; his work on *Infection and Resistance* and later his work on *Resistance to Infectious Diseases*, published in 1931, and last year a new edition of his work on *Immunity*. In the midst of his scientific career, in which he achieved recognition as one of the foremost bacteriologists of our times, he took part in the campaign

against typhus and had recently announced the development of a technic for the mass production of vaccine against this plague.

Coincidentally he produced in 1935 his book on "Rats, Lice and History," which became a best seller. He was a philosopher, historian, poet and wit, and he had contributed poetry to many leading periodicals. This year appeared the biography of R. S. under the title "As I Remember Him," in which he described in the third person the life of Hans Zinsser. The book became at once a nonfiction best seller and was the choice of the Book of the Month Club for July. Not only are the initials R. S. the last letters of his name, Hans Zinsser, but they were chosen also because they meant to him "romantic self." The paragraphs in which he wrote of his own death are a remarkable contribution. He wrote:

Something took place in his mind that he regarded as a sort of compensatory adjustment to the thought that he would soon be dead. In the prospect of death, life seemed to be given a new meaning and fresh poignancy. . . . From now on, instead of being saddened, he found—to his own delighted astonishment—that his sensitiveness to the simplest experiences, even for things that in other years he might hardly have noticed, was infinitely enhanced. . . .

As the disease caught up with him R. S. felt increasingly grateful for the fact death was coming to him with due warning, and gradually. So many times in his active life he had been near sudden death by accident, violence or acute disease; and always he had thought that rapid and unexpected extinction would be most merciful. But now he was thankful that he had time to compose his spirit and to spend a last year in affectionate and actually merry association with those dear to him.

Dr. Hans Zinsser was a courageous investigator, the possessor of an extraordinary mind, a tolerant, judicial, scientific leader. His contribution to the world was significant. His death at the early age of 61, no doubt, deprives mankind of many another work of permanent importance.

HANS ZINSSER, M.D., 1878-1940

Charles Bert Reed ☉ Chicago; Rush Medical College, Chicago, 1887; member of the House of Delegates of the American Medical Association from 1933 to 1940 and delegate at special sessions in 1935 and in 1938; demonstrator of obstetrics at Northwestern University Medical School from 1903 to 1906, assistant professor from 1906 to 1912 and associate professor since 1931; past president of the Illinois State Medical Society and the Chicago Medical Society; treasurer of the Chicago Gynecological Society from 1904 to 1909 and from 1910 to 1929 and president 1909-1910; fellow of the American College of Surgeons; chief obstetrician to

the Wesley Memorial Hospital; attending obstetrician to the Cook County Hospital from 1902 to 1906; author of textbooks entitled "Obstetrics for Nurses" and "Operative Obstetrics on the Manikin" and many others; aged 74; died, September 3, in Sand River, Ont., of heart disease.

Maurice Oliver Magid ☉ New York; Cornell University Medical College, New York, 1905; past president of the Bronx County Medical Society, the Bronx Gynecological and Obstetrical Society; the New York Physicians' Association; chairman and formerly secretary of the Joint Committee of the Organized Medical and Dental Professions of the City of New York; at one time instructor in gynecology at the New York Polyclinic Medical School and Hospital; aged 57; was a director, chairman of the medical board and a founder of the Hunts Point Hospital; on the staff of the Bronx Hospital, where he died, July 31.

William Vincent Whitmore, Tucson, Ariz.; University of Southern California College of Medicine, Los Angeles, 1890; member of the House of Delegates of the American Medical Association in 1910; past president of the Arizona State Medical Association and the Pima County Medical Society; for many years member of the school board; formerly member of the

board of regents of the University of Arizona; aged 78; died, July 24.

William M. Cole, Long Beach, Calif.; Manitoba Medical College, Winnipeg, Man., Canada, 1913; member of the California Medical Association; fellow of the American College of Physicians; served with the Canadian Army during the World War; on the staffs of the Seaside Memorial Hospital, St. Mary's Hospital and the Community Hospital; aged 48; died, July 9, in the Compton (Calif.) Sanitarium of coronary sclerosis.

Otto H. Crist, Danville, Ill.; Northwestern University Medical School, Chicago, 1906; member of the Illinois State Medical Society; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; past president of the Wabash Valley Aesculapian Society; on the staffs of the Lakeview and St. Elizabeth's hospitals; aged 61; died, August 7, of coronary thrombosis.

Frank A. Stubblefield, Brighton, Ill.; Missouri Medical College, St. Louis, 1882; physician at the Jacksonville (Ill.) State Hospital from 1902 to 1914 and the Alton (Ill.) State Hospital from 1914 to 1916, when he was appointed managing officer of the Chester State Hospital, Menard, where he served until 1934; aged 84; died, July 27, at the Alton (Ill.) Memorial Hospital of cardiorenal disease.

Marion R. Hammer, Newton, Iowa; Northwestern Medical College, St. Joseph, Mo., 1881; King Eclectic Medical College, Des Moines, 1889; member of the Iowa State Medical Society; past president of the Jasper County Medical Society; formerly city physician and county coroner; on the courtesy staff of the Mary Frances Skiff Memorial Hospital; aged 87; died, July 11, of cerebral hemorrhage.

Cloyce Robert Tew, Raleigh, N. C.; Johns Hopkins University School of Medicine, Baltimore, 1931; member of the Medical Society of the State of North Carolina; fellow of the American College of Surgeons; secretary of the Wake County Medical Society; on the staff of the Rex Hospital; aged 33; died, July 11, of a self-inflicted bullet wound.

Thomas Jefferson Marcus, Clanton, Ala.; Memphis (Tenn.) Hospital Medical College, 1910; member of the Medical Association of the State of Alabama; past president and secretary of the Chilton County Medical Society; aged 69; on the staff of the Central Alabama Hospital, where he died, July 30, of heart disease.

Alex Malcolm Macaulay @ Great Falls, Mont.; Manitoba Medical College, Winnipeg, Man., Canada, 1907; fellow of the American College of Surgeons; served during the World War; member of the visiting staff of the Columbus Hospital; aged 63; died, July 23, in Conrad of gangrenous appendicitis.

Joseph Edward Gately @ Baltimore; University of Maryland School of Medicine, Baltimore, 1902; served during the World War; aged 60; on the staffs of the Johns Hopkins Hospital and St. Joseph's Hospital, where he died, July 21, of cerebral hemorrhage, embolism and coronary infarction.

James Rufus Rogers, Raleigh, N. C.; College of Physicians and Surgeons, Baltimore, 1886; member of the Medical Society of the State of North Carolina; aged 73; for many years on the staff of the Rex Hospital, where he died, July 5, of acute mesenteric thrombosis and diabetes mellitus.

Charles R. Teeter, Russellville, Ark.; University of Arkansas School of Medicine, Little Rock, 1907; member of the Arkansas Medical Society; for many years member of the school board of Pottsville; aged 65; died, July 13, in St. Vincent's Infirmary of carcinoma of the right kidney.

Frank H. Green @ Rushville, Ind.; University of Indianapolis Medical Department, 1897; past president of the Rush County Medical Society; formerly county coroner; served during the World War; owner of a hospital bearing his name; aged 63; died, July 30, of carcinoma of the liver.

Rollin John Smith, Appleton City, Mo.; Missouri Medical College, St. Louis, 1887; member of the Missouri State Medical Association; aged 79; died, July 20, in the Trinity Lutheran Hospital, Kansas City, of hypertensive cardiovascular disease, cerebral hemorrhage and arteriosclerosis.

Charles Alex Van Slyke @ St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1891; an Affiliate Fellow of the American Medical Association; aged 75; died, July 21, in St. Joseph's Hospital of bronchopneumonia following a fracture received in a fall.

Daniel Sayer Hardenberg, Jersey City, N. J.; Columbia University College of Physicians and Surgeons, New York,

1904; member of the Medical Society of New Jersey; aged 60; on the staff of the Christ Hospital, where he died, July 28, of hypertensive heart disease.

James Moffatt Alexander, Statesville, N. C.; Georgetown University School of Medicine, Washington, D. C., 1925; member of the Medical Society of the State of North Carolina; aged 39; died, July 6, in Broadoaks Sanatorium, Morganton, of chronic myocarditis.

William Herbert Wardell, Moose Jaw, Sask., Canada; Manitoba Medical College, Winnipeg, 1902; fellow of the American College of Surgeons; on the staffs of the Moose Jaw General and Providence hospitals; aged 69; died, June 4, of carcinoma of the stomach.

Robert Walter Frischkorn, Washington, D. C.; George Washington University School of Medicine, Washington, 1904; veteran of the Spanish-American War; aged 64; died, August 2, in the Providence Hospital of acute nephritis and coronary occlusion.

Charles Walice Gardner, Mount Pleasant, Iowa; College of Physicians and Surgeons, Keokuk, 1894; member of the Iowa State Medical Society; aged 82; died, July 26, in the Mercy Hospital, Burlington, of hypertrophy of the prostate and heart disease.

Martin Luther Bomberger, Lebanon, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1940; aged 30; intern at the Harrisburg (Pa.) Hospital, where he was found dead in bed, July 8, of a self-inflicted incised wound of the throat.

Francis Evans Wynne @ Baxter Springs, Kan.; University of Kansas School of Medicine, Kansas City, 1933; president of the Cherokee County Medical Society; aged 31; died, July 30, in the McCune-Brooks Hospital, Carthage, Mo., of poliomyelitis.

Bernard Andrew Bailey, Wiscasset, Maine; Dartmouth Medical School, Hanover, N. H., 1890; member of the Maine Medical Association; served during the World War; aged 70; died, July 18, of cerebral embolism and chronic nephritis.

Joseph Payson Clark, Boston; Harvard Medical School, Boston, 1887; member of the Massachusetts Medical Society; past president and treasurer of the American Laryngological Association; aged 80; died, July 21, of arteriosclerosis.

Joseph Maurice Jackson, Pittsburgh; Columbia University College of Physicians and Surgeons, New York, 1899; for many years on the staff of the Montefiore Hospital; aged 63; died, July 31, in Long Beach, Calif., of coronary thrombosis.

Robert Maclay Smith, Gonzales, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1909; member of the Louisiana State Medical Society; aged 57; died, July 28, in Jackson of a fracture of the hip and pneumonia.

Eugene Rankin Cocks, Asheville, N. C.; Jefferson Medical College of Philadelphia, 1913; member of the Medical Society of the State of North Carolina; served during the World War; aged 53; died, July 14, of mesenteric thrombosis.

Bernard Edward Bauman, St. Louis; St. Louis University School of Medicine, 1936; resident in tuberculosis at the Mount St. Rose Sanatorium; aged 34; died, August 4, of an injury received when he dived into shallow water.

John Thomas Guynes, Jourdanton, Texas; University of Tennessee College of Medicine, Memphis, 1914; member of the State Medical Association of Texas; health officer; aged 57; died, July 21, of coronary occlusion.

Myron Preston Denton @ New York; Harvard Medical School, Boston, 1887; an Affiliate Fellow of the American Medical Association; aged 80; died, July 22, in the General Hospital, Saranac Lake, of uremia.

James Henry Johnson, Hillsdale, Mich.; Detroit College of Medicine, 1897; member of the Michigan State Medical Society; served during the World War; aged 64; died, July 31, of lung tumor and abscess.

Harvey D. Miller, Myerstown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1896; aged 68; died, July 31, in St. Joseph's Hospital, Reading, of coronary and cerebral sclerosis.

Frank Lester Bigsby, Kirksville, Mo.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901; served during the World War; aged 62; died, July 27, of arteriosclerosis.

Toby Anthony Greco, Margate City, N. J.; Jefferson Medical College of Philadelphia, 1916; member of the Medical Society of the State of Pennsylvania; aged 46; died, July 18, of coronary occlusion.

Correspondence

THE TREATMENT OF POLYCYTHEMIA BY THE INDUCTION OF AN IRON DEFICIENCY STATE

To the Editor:—Reznikoff (*THE JOURNAL*, July 27, p. 298) has recently questioned the rationale of our method of treatment in polycythemia (Dameshek, William, and Henstell, H. H.: *J. Clin. Investigation* 16:683 [July] 1937; *Ann. Int. Med.* 13:1360 [Feb.] 1940), which combines systematic phlebotomy with a low intake of iron. He states that "most of these patients have a fairly normal color index, . . ." which is directly contrary to our experience and that of others, and that he does not understand "why cutting the iron down inhibits cell production. . . ."

What one must aim for in the rational treatment of the disease is not simply reduction in red cell count but reduction of the total red cell mass, as Haden (*Am. J. M. Sc.* 196:493 [Oct.] 1938) puts it. In this endeavor the greatest emphasis is laid on the figures for hemoglobin, hematocrit and red cell volume with but little reference to the red cell count. Our method, which has now been in successful use for more than five years, is based on the development of an iron deficiency state through a series of systematic venesections and its prolongation by the use of a diet low in iron.

In a fresh case of polycythemia (hemoglobin 140 per cent, red blood cells 9 million, hematocrit 75 per cent) venesections of 500 cc. of blood are performed twice a week until the hemoglobin content is reduced to approximately 80 to 85 per cent, red blood cells from 5 to 5.5 million, and the hematocrit reading from 42 to 45 per cent. Ordinarily, this requires from six to eight venesections. The patient is then given a diet low in iron, containing approximately 6 mg. of iron a day. This requires avoidance of red meat, meat soups, liver, eggs, rye bread and brown cereals. Fowl once a week, fish twice a week, cheese, milk and legumes give sufficient protein.

The method was instituted because of our disappointment with the uncertainties and dangers inherent in the use of x-rays, phenylhydrazine, acetyl phenylhydrazine and solution of potassium arsenite as well as through a fortuitous circumstance. One of our patients, poorly controlled with the measures mentioned, had an unusually severe hematemeses—due to peptic ulcer—and was placed on a Sippy regimen. It was noted that, although the red cell count rose to fairly high levels after a few months, the hemoglobin concentration remained consistently low. What is more, there was complete relief in all the symptoms of the polycythemic state. It was reasoned that a state of chronic hypochromic "anemia" (hemoglobin 70 per cent, red blood cells 5-6-7 million) had been induced by means of hemorrhage combined with the low iron content of the orthodox Sippy diet.

It was therefore proposed to imitate severe hemorrhage in other cases of polycythemia by performing venesections twice a week for several weeks. This procedure, particularly when combined with a low dietary intake of iron, results in a loss of hemoglobin from the body and ultimately in a depletion of the bodily stores of iron. Such a method has for many years been successfully used by Whipple and his collaborators in their colony of anemic dogs, and its results are analogous to the condition found in chronic "primary" or "idiopathic" hypochromic (iron deficiency) anemia of adult women. Reductions are obtained in the color index, mean corpuscular volume, mean cell diameter and mean corpuscular hemoglobin concentration. These reductions become more pronounced as the red cell count begins to rise, while the hemoglobin and hematocrit percentages remain at fairly constant levels. It is apparent that, although the bone marrow continues to produce unusually large numbers

of erythrocytes, the lack of sufficient iron within the body must necessarily result in a diminution in hemoglobin concentration of each individual red cell and in the production of small red blood cells. As a result, the hemoglobin concentration in the blood remains low and the red cells become more and more hypochromic and small. Thus from six to twelve months after a series of venesections it is not unusual to see figures such as these: hemoglobin 85 per cent, red blood cells 8.5 million, color index 0.5, hematocrit 50 per cent, mean corpuscular volume 60 cubic microns, mean cell diameter 6.5 microns.

Under such circumstances the outcome of the red cell count becomes a minor consideration. Of major importance are the hemoglobin and hematocrit percentages. With low values for hemoglobin the hematocrit percentage is necessarily low whatever the red cell count, and low or normal values are obtained for blood viscosity, total blood volume, red cell volume and red cell mass. When all these figures are either low or normal, the numerous symptoms of polycythemia usually disappear completely, to return when the hemoglobin and hematocrit percentages again become definitely increased (usually within six to twelve months).

As Minot and Castle (1939 Year Book of General Medicine, p. 329) state: "Treatment of the disease has recently become distinctly more satisfactory because of recognition of the physiologic basis of the beneficial effects of repeated venesections and its consequent more intelligent application. . . . Repeated bleedings . . . eventually lead to the development of a hypochromic blood picture with, as in any form of chronic blood loss, diminished blood regeneration." From the physiologic standpoint it would seem likely that restriction of the iron content of the diet would help to maintain a chronic state of iron deficiency. This has not yet been entirely established, although we have evidence that such reduction prolongs the period of remission between venesections (average eight months in our cases).

WILLIAM DAMESHEK, M.D., Boston.

RETENTION CATHETER OR INTERVAL CATHETERIZATION

To the Editor:—The discussion by Dr. Samuel N. Vose of Boston (*THE JOURNAL*, August 10, p. 475) of my paper (*ibid.*, June 15, p. 2368) disagrees with abolition of the retention catheter in preoperative preparation of prostatic patients. Since the point at issue has a rather important bearing on the care of thousands of patients in our hospitals annually, it is to be hoped that others besides Dr. Vose will make and report observations to sustain or refute my contention that interval catheterization should supersede the retention catheter. I am convinced that the almost universal use of the retention catheter is due to uncritical acceptance of the dictums of the past and that the custom will not stand the test of clinical comparison with intermittent catheterization.

To take up the specific points of Dr. Vose's discussion, I must express my doubt concerning the adequacy of the measures for management of the retention catheter on which he relies to prevent complications. The shortcomings of the retention catheter are not to be overcome by attention to such details as shaving the pubic hair and closed irrigating systems, laudable as these all may be. There is doubtless a certain advantage in the self-retaining balloon catheter which Dr. Vose prefers, but external retaining devices properly applied cannot justly be blamed for the febrile episodes and purulent urethritis so commonly associated with use of the retention catheter. No refinement of technic can hope to secure absolutely aseptic insertion of a catheter; the anterior urethra itself is not usually sterile (Schulte, T. L.: *Newer Methods in a Study of the Bacteriology of the Urinary Tract*, *Proc. Staff Meet., Mayo Clin.* 14:249

[April 19] 1939), and least of all that of prostatic patients, who often have been carelessly catheterized before entering the hospital. The basic fault of the retention catheter is that it continuously and harshly traumatizes the urethra. Gross infection then inevitably follows in spite of all care.

Dr. Vose thinks that extremely small retention catheters (even No. 12 French) would suffice for vesical drainage and would allow ample space for the escape of "secretions" around the catheter. I have grave misgivings as to the reliability of so small a catheter, and Dr. Vose admits that in actual practice he uses a No. 16 French catheter. This is in accord with common practice. In any case I feel that, within reasonable limits, the caliber of the retention catheter is not a crucial point. Small or large, a retention catheter, like a cinder in the eye, is a harmful and unpleasant irritant. Dr. Vose concedes this by implication when he stresses the matter of drainage around the catheter. Under a regimen of interval catheterization there need be no concern about urethral drainage, since there will be no discharge, purulent or otherwise.

It is unfortunately not possible to carry out a controlled experiment to settle this question, but the conditions of such a study can easily be postulated. Two sizable groups of healthy young men free from all evidence of infection of the urinary tract would voluntarily submit themselves to a prolonged period of vesical drainage, in the one case with the retention catheter and in the control group with interval catheterization. My experience convinces me that the retention catheter group would show a much higher incidence of complications—in other words that the retention catheter is a device well calculated to make even a well man sick.

My memory carries back to numerous old men who entered various hospitals and proceeded to lapse into febrile coma and die after installation of the retention catheter. These patients never came to surgery and therefore never figured in the mortality tables of prostatic operations; but they were an important element in the total mortality rate of prostatism. Death certificates described the immediate cause of death as "urcemia." The rarity of similar cases in my present practice has made me believe that sepsis induced by the retention catheter was a large contributing factor in these deaths.

In personal discussions of interval catheterization of prostatic patients at a recent urologic meeting, several urologists expressed approval of the idea but declared they considered it unfeasible because interns would object to such drudgery. I do not think it necessary or fair to ask interns to assume a task which can be so easily made a routine. Intelligent orderlies quickly learn to perform this duty in a thoroughly satisfactory way. Interval catheterization has seemed so obviously superior and has been so eminently gratifying that I would urge all urologists at least to give it a trial.

RICHARD P. MIDDLETON, M.D., Salt Lake City.

MYASTHENIA GRAVIS

To the Editor:—The report of an apparently miraculous recovery from myasthenia gravis following implantation of pellets of synthetic adrenal hormone (*THE JOURNAL*, July 13) will not impress many who are familiar with the disease. The diagnosis in the case may be questioned; furthermore, limited observations on a single case are not convincing.

The young physician thought to be the victim of myasthenia gravis presented symptoms which suggest the results of nervousness and anxiety. It is common for nervous medical students and young physicians to acquire the symptoms of any disease which they happen to study. Did this patient recover from myasthenia gravis or merely from nervous manifestations which simulated it?

A recent editorial in *THE JOURNAL* pointed out the possible dangers from the indiscriminate use of desoxyeorticosterone acetate and condemned the clinical use of the material in conditions in which it had not been proved to be of value. Should not this warning be applied to the use of the material in myasthenia gravis?

FRANK N. ALLAN, M.D., Boston.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

"INTESTINAL FLU"

To the Editor:—The clinician tells us there is an entity of "intestinal flu." The bacteriologist says there isn't. Please clarify this problem.

M.D., Ohio.

ANSWER:—Since the term "intestinal flu" is almost entirely of clinical use, the bacteriologist has not been in a position to pass on its validity. There are apparently outbreaks of disease in which gastrointestinal symptoms and abdominal pain are prominent. This set of symptoms is, however, extremely uncommon in epidemics of influenza. In most instances the so-called intestinal flu is found to be due to water-borne or food-borne bacterial infection. There is little justification for the continued use of the term, since it implies associations which are unwarranted.

ECZEMA OF AUDITORY CANAL

To the Editor:—Can you give me suggestions as to the treatment of eczema of the auditory meatus, of many years' standing, in a woman 54 years old? There is so much thickening of the tissues that the opening is practically closed. Blood pressure and other conditions are normal, though the patient is definitely overweight. Is resection or cautery ever justifiable in opening up the canal? It would seem unpractical, but the woman wishes to hear, and it is difficult to do so with the canals closed.

Melvin A. Drake, M.D., Buhl, Idaho.

ANSWER:—So-called eczema of the auditory meatus differs from dermatitis elsewhere in its inaccessibility and because of the danger of swelling closing the canal. The meatus offers a lodging place for infection from without or from the middle ear and its accumulation of wax and epithelial debris makes a good culture medium for various organisms, saprophytic or pathogenic. These peculiarities must be added to the usual difficulties of an itching dermatosis, eczematoid in character. One must consider (1) contact dermatitis, (2) infectious eczematoid dermatitis, (3) certain forms of dermatitis medicamentosa, (4) neurodermatitis, (5) the result and only outward manifestation of some metabolic disturbance such as an upset sugar metabolism or liver dysfunction, (6) a part of one of the commoner scaly dermatoses such as psoriasis or seborrheic dermatitis, (7) part of one of the rarer cutaneous or general diseases as lymphoblastoma, and (8) a combination of two or more of them.

In a case in which the ear canal is the only part of the skin involved, as is assumed for the case under discussion, the probability lies strongly with the second of these possibilities and a careful search for fungi and bacteria is in order. The scales should be examined for fungi, the exudate for both fungi and bacteria. Before making cultures the canal should be thoroughly cleansed to get rid of most of the saprophytes. E. J. Walen (*Fungus Infection of the External Ear*, *THE JOURNAL*, Aug. 6, 1938, p. 502) prefers an alcoholic solution of sodium sulfide for the scales because the ordinary hydroxide solution dissolves some of the fungi. For culture of fungi he uses Sabouraud's or Shaw's medium.

Cultures for bacteria are also important as described by J. H. Mitchell (*Streptococcus Dermatitis of the Ears*, *THE JOURNAL*, Jan. 30, 1937, p. 361). The frequency with which an infectious eczematoid dermatitis of the face originates from an ear canal infection is not to be denied. Williams, Montgomery and Powell studied a series of cases of ear dermatitis (*Dermatitis of the Ear*, *THE JOURNAL*, Aug. 19, 1939, p. 641). In some they found fungi, in others bacteria and in still others a mixture of these two forms of plant life.

On another occasion Mitchell warned against the use of any but the most soothing of drugs in treating cutaneous infections

without a preliminary patch test of each drug, to protect against the possibility of adding a contact dermatitis to the picture. This is a wise and practical measure. The infection may have found its opportunity to localize in a preexisting sensitization dermatitis. Some years ago White suggested that fungous infections predispose to sensitizations.

Swelling of the walls of the canal can usually be reduced by the use of glycerin tampons, increased in size as the canal is dilated. If the skin is oozing, painting with silver nitrate solution 10 to 50 per cent will often dry it.

The fourth possibility listed must not be forgotten in treating any itching disease, for while primary neurodermatitis is a common skin disease, the neurotic element has to be considered in every case of itching. Rubbing with the finger in the ear canal, or often with more dangerous instruments such as hairpins, can be taken for granted in any case of itching until the patient has been warned of its harmful effect. Even then only those with the greatest self control can resist the urge to scratch or rub. A substitute action must be provided in the application of a soothing lotion such as 1 per cent phenol in alcohol. This should be dropped into the canal in small amounts, or if swabbing is desired the patient or nurse must be warned against the slightest unnecessary rubbing.

Ointments are less satisfactory in the ear canal than elsewhere. Two per cent gentian violet solution in water is an effective antiseptic in many cases and unlikely to cause irritation. Roentgen rays may be found helpful in reducing the inflammation and itching. They may be used in divided doses, 75 roentgens once a week. Some patients get a lasting result from such treatment, but oftener it proves to be only a temporary help. It has the disadvantage that the amount of treatment that can be given with safety is strictly limited and that no irritating applications of any kind can be used with safety in conjunction with roentgen rays or within three weeks after the course of irradiation has ended.

Surgical measures such as those suggested are seldom justified and often lead to further trouble.

UNUSUAL ALOPECIA AREATA

To the Editor:—A 12 year old girl of Polish extraction complained at intervals of complete alopecia, occurring two or three times a year for the past eight years. Loss of hair takes about one week to be complete and is usually accompanied by mild right frontal headache and slight fever. Following the loss of hair, regeneration seems to have been rapid. There is no association with season or other illness. The only illness in the past history was measles at the age of 2 years, with no apparent complications. The family history is entirely negative. She gets along well in school and is in the sixth grade. Menstrual onset has not yet appeared. The patient is rather poorly nourished, with a fair complexion. Her appearance is bright. Skin turgor is good. The scalp hair is dry and brittle and shorter over the occiput. There are no areas of patchy alopecia and no inflammation of the scalp. Eyebrows and eyelashes are normal in texture. There is no hair growth anywhere on the trunk or the extremities. Pupils are equal and react to light and in accommodation. Visual fields are roughly within normal limits. Eyegrounds are normal. The throat, ears, nose and neck are normal. The breasts are entirely flat. The heart, lungs, abdomen and extremities reveal no abnormality, and there are no neurologic abnormalities. The blood pressure is 115 systolic, 85 diastolic. The pulse is 80 and regular. The temperature is 98.8 F. The basal metabolic rate is +14. The blood count is within normal range and analysis of the urine gives negative results. A roentgenogram of the skull shows "moderate digitation over the inner table that would support clinical evidence of increased intracranial pressure. The sella turcica is normal in size and contour." I would appreciate any suggestions as to treatment or references. M.D., Illinois.

ANSWER:—This appears to be an unusual type of alopecia areata. The inquirer does not state what the appearance of the scalp was during the phases of loss of hair. One would want to know whether there was any inflammation present. It is not stated whether hairs, such as of the eyebrows and the eyelashes, participated in the process. It is not uncommon for the latter hairs to fall when all the scalp hairs are lost. Alopecia areata may recur after complete restoration of the hair, but its repetition three times a year for eight years is certainly extraordinary. It would be more usual for the process to be continued for years with new areas forming as old ones become covered with hair.

There is no new literature of significance pointing to either cause or cure of this disorder. The older theories that have been mentioned in the past continue to be invoked. They are the toxic, parasitic, trophic and endocrine theories.

Thallium is capable in proper dosage of effecting the loss of hair such as takes place in this case. Since thallium is incorporated in rat poisons, it may be worth while to inquire into the possibility of accidental thallium absorption. Foci of infection in teeth, tonsils or sinuses may be present. Jacquet stressed reflex irritation as a cause of alopecia areata. He mentioned especially defective teeth. Any source of irritation

should therefore be sought for and eliminated. The basal metabolic rate is slightly above the upper limit for normal, which suggests that the test should be repeated. If the rate remains high in the second test, the administration of compound solution of iodine could be tried.

Syphilis is sometimes said to be a cause of alopecia areata. A blood serum test for syphilis should accordingly be made. If the periods of defluvium could be determined in advance, it might be helpful to use stimulating lotions on the scalp just prior to the expected event. A solution of mercury bichloride in the strength of 1:300 or 1:500 may be useful for this purpose. This application has a drying effect, and because this girl's hair is already dry and brittle castor oil should be added to the lotion. The periodic defluvia suggest as a possibility a peculiar form of erythema multiforme-like condition, which too tends to be periodic in its appearance. It might be well, then, to administer salicylates before an expected defluvium. Lastly, there are reports in the literature of shedding of the skin at regular intervals. This phenomenon is regarded as a form of atavism. This periodic loss of scalp hair may perhaps be likewise regarded. In such a case, nothing proposed would be expected to be of much benefit.

CHRONIC DIARRHEA AND PARATYPHOID BACILLI IN STOOLS

To the Editor:—Could you suggest treatment for a chronic diarrhea of twelve years' duration? Stool cultures show paratyphoid A and B. The patient is passing some blood and is having from eight to twelve stools daily. M.D., New Mexico.

ANSWER:—It must be remembered that diarrhea is always a symptom and never a disease. The finding of paratyphoid bacilli in the stool culture only confuses the issue and means only that this patient is a paratyphoid carrier. Has the patient ever had clinical paratyphoid fever?

The common infectious causes of diarrhea of long standing are amebic dysentery, bacillary dysentery, ulcerative colitis, tuberculous enteritis and parasitic infestation. There are a number of noninfectious causes but relatively few of these would go undiagnosed for twelve years. Sprue must be considered. Pancreatic disease is a possibility. It is not likely that a patient with carcinoma of the bowel would survive for twelve years but with benign neoplasm might do so.

It seems hardly likely that pernicious anemia, leukemia, Addison's disease or one or two other causes would exist for twelve years without being recognized one way or another.

Since there is bleeding there is probably ulceration of the bowel. Proctoscopy to bring the ulcer under observation seems to be the first indication. It is possible that a diagnosis may be made from the appearance of the ulcer. Scrapings from the ulcer may be used for microscopic examination and culture. The proctoscopic examination would determine the advisability or need for x-ray examination of the bowel.

Only when a diagnosis is reached can suggestions for treatment be offered.

Nothing is said about the general condition of the patient. As a rule such patients are emaciated, dehydrated and anemic and show evidence of vitamin deficiency. All of these things must be treated while the fundamental cause is being determined.

ESTROGENIC THERAPY AND BLOOD CHOLESTEROL

To the Editor:—A patient with menopausal symptoms is taking 0.12 mg. of estriol (Theelol) by mouth daily and 10,000 international units of estrone (Theelin) hypodermically twice a week. Blood cholesterol determination by the method of Bloer revealed 303 mg. per hundred cubic centimeters. It is my understanding that the estrogens are closely related chemically to cholesterol. Could the elevated cholesterol reading be accounted for by the estrogenic drugs she is taking? Unfortunately, no cholesterol determination was made before instituting this treatment. The basal metabolic rate before treatment was -25. Symptoms are so numerous and atypical that they cannot be interpreted as suggestive of a hypothyroid state. M.D., Alaboma.

ANSWER:—Cholesterol is an essential constituent of all cells and fluids of the body. It belongs to the class of sterols, being chemically related to bile acids, calciferol, estrogen, androgen and progesterone.

The normal limits of blood cholesterol may vary from 120 to 200 mg. per hundred cubic centimeters. There are wide and rapid fluctuations even in the fasting state. Ingestion of fats, butter, eggs and meat increase blood cholesterol. It is said that 50 per cent of pregnant women show an increase in blood cholesterol in the latter half of pregnancy.

In myxedema and hypothyroidism the blood cholesterol ranges from 225 to 750 mg. per hundred cubic centimeters. The patient in question has a blood cholesterol level of 303 mg. Her basal

metabolic rate is —25 per cent, which could easily account for the increased cholesterol.

It is doubtful that the injection of estrogen had much influence on the moderately increased cholesterol in the case mentioned. It is more reasonable to suppose that the moderate hypothyroidism as shown by the basal metabolic rate had a more determining influence on this increase.

The dose of estrogen given to this woman seems large. It is advisable to give 2,000 international units of estrone three times weekly, plus thyroid to the tolerance limit. Larger doses of estrone may be given if this dosage does not produce satisfactory relief.

SCIATIC NERVE INJECTION

To the Editor:—I have learned from German refugees that they use an ampule preparation of antipyrine, scopolamine and atropine for injection into the sciatic nerve in sciatica. Excellent results are claimed from two or three injections. Where can I obtain such material in the United States? What is the technic for sciatic nerve injection?

Alexander Winter, M.D., New York.

ANSWER.—The injection treatment of sciatica is old. The technic of perineural injection in the buttock by the method of Lange of Leipzig (1904) was described by the late D'Orsay Hecht in *THE JOURNAL*, Feb. 6, 1909. A line is drawn from the junction of the sacrum and coccyx to the posterolateral external border of the greater trochanter. A stout needle is introduced at a point a thumb's width outside the junction of the inner and middle thirds of the line mentioned. The patient is asked to tell when the nerve is reached, as he gets a more or less painful sensation all the way to the heel. Today one generally first injects a little 1 or 2 per cent procaine hydrochloride followed by about 80 cc. of physiologic solution of sodium chloride.

Later Cathelin recommended epidural injection of procaine hydrochloride and physiologic solution of sodium chloride in the sacral foramen. The method was fully described by Israel Strauss in *THE JOURNAL*, Dec. 15, 1917. Following the procaine hydrochloride from 60 to 80 cc. of physiologic solution of sodium chloride is injected. By either method three injections two or three days apart are generally required. In 1922 Höglér recommended injection of 10 cc. of 40 per cent warm antipyrine solution in the sacral canal. This method as well as injection of oxygen was described by J. P. Martin in the *Lancet*, May 22, 1926. It would not seem necessary to secure the German ampules mentioned, as a safe amount of scopolamine and atropine might be added to Höglér's antipyrine solution.

DISCOID LUPUS ERYTHEMATOSUS

To the Editor:—A girl aged 14 had a severe case of rhus poisoning three years ago. While the dermatitis on her hands soon disappeared, her face since that time has had many red oval patches covered with moderate slight scale formation. The patches are slightly elevated at their edges, somewhat depressed and atrophic appearing in their centers. There have never been any papules or vesicles in these patches. At present "patulous gland openings" are not readily discernible. There are all told nine patches on her face and three on her scalp, with loss of hair in these regions. The patches on both face and scalp have varied little in shape, size or appearance during the past three years in spite of many attempts at external therapy. The lesions do not itch, which suggested lupus erythematosus to me. These patches are sharply circumscribed. How effective is sodium gold thiosulfate in lupus erythematosus? Is external therapy of any value? The girl is in excellent health otherwise. The Kahn and Pirquet tests are negative. M.D., Illinois.

ANSWER.—The description fits discoid lupus erythematosus quite well. The peglike keratotic plugs may be discovered on the under side of the scales. The negative Pirquet reaction is an exception to the rule for lupus erythematosus but does not rule it out. The only other diagnosis likely would be that of sarcoid; but this seldom occurs at the age of 14. Before undertaking the treatment, however, it would be advisable to have the diagnosis confirmed by an experienced dermatologist.

Assuming a diagnosis of lupus erythematosus, the patient and her parents should be warned against exposure to strong sunlight or ultraviolet rays. The physician must watch also for the appearance of lesions on the upper part of the chest in the V exposed by the clothing to the action of light or on the fingers, hands or arms, for these are the signs of dissemination, indicating a much more dangerous form of the disease.

The urine must be examined frequently for albumin and casts, for kidney involvement is likewise a complication that adds much to the seriousness of the case. Frequent examinations of the blood are also necessary.

It is always difficult to know which method of local treatment may succeed in any given case. The internal administration of quinine in the maximum tolerated dose combined with external application of tincture of iodine to the lesions once a day is

sometimes successful. A test dose of quinine should be given first, to rule out hypersensitiveness to the drug, and the signs of intolerance should be watched for during the treatment. Frequent rests from treatment are made necessary by the local reaction to iodine. Painting the lesions once a week with a mixture of 1 part of phenol and 4 parts of strong lactic acid may be valuable. The burning sensation does not last long and the local reaction is usually not excessive. In resistant cases, freezing with solid carbon dioxide at weekly intervals or less often, according to the strength of the reaction, is a valuable measure and if done with discretion does not make scars any greater than the lesions would leave under any method of treatment. From five to twenty seconds under fair pressure is usually enough. Radium applied superficially is also productive of good results in some cases. A mild reaction is usually necessary to obtain cure of the lesion, and the exact location must be recorded to protect against overdosage on this spot in case of recurrence. In this case also care must be exercised if carbon dioxide treatment is desired at a later date, for skin that has been subjected to the rays of radium or the x-rays may later be sensitive to freezing because of the damage to the blood vessels.

If all these methods of local treatment fail, it may be necessary to use general treatment. Intramuscular injections of bismuth salts may be carried out just as in the treatment of syphilis.

The treatment with salts of gold has become a standard method of management but there are many cases that will yield to milder measures, and gold therapy is not in any sense a minor form of treatment. It is comparable to the arsphenamine treatment of syphilis, and its toxic manifestations are somewhat more serious than those seen after arsphenamine. Leukopenia and sometimes granulocytopenia are of serious import and may be signalized by hemorrhages into the skin or from the mucous membranes. Cutaneous eruptions of various kinds, morbilliform, urticarial or scarlatiniform, may, if the treatment is not promptly stopped, progress to serious exfoliative dermatitis. The urine must be examined for albumin and casts before each dose, and the white blood cells should be counted every week or two. The physician has a double problem, a disease characterized by a tendency to sensitization and a drug which is noted for its sensitizing ability.

CARE OF ABDOMINAL COLOSTOMY

To the Editor:—Judging from my own experience, there is a great paucity of information on how to care for a patient with an abdominal colostomy. I would like to know how to advise a patient what to do to alleviate a condition which usually makes the victim virtually a pariah. 1. What position should he take for evacuation, lying down prone, or should suction be employed? How about a pus basin? 2. What diet is recommended? 3. Is irrigation recommended at regular intervals? 4. If the opening is made through the rectus abdominis, may this act as a sphincter? What is the objection? 5. Pastes are used to seal the colostomy pad. What is aluminum paste? 6. What can be done about loose stools, flatulence, fecal odor and the like? 7. Is there a good colostomy pad on the market?

Thomas I. O'Drain, M.D., Philadelphia.

ANSWER.—A patient with an abdominal colostomy is not ordinarily in any way interfered with in the performance of his ordinary social or business duties. All that is required is a little attention to a system, in which even the patient is able to carry on as well as anybody.

1. The patient is usually advised to take an enema of three glasses of water every morning, lying on the back end of the bathtub. A catheter inserted into the colostomy is threaded through an ordinary baby's nipple, the sucking end of which is inserted into the colostomy and acts as a water valve. After the three glasses of water has been taken the patient sits up, places a basin beneath the colostomy, gently massages the abdomen and thoroughly evacuates the large bowel.

2. The patient is advised to abstain from laxative food for the first few months after operation, taking only enough fruit and vegetables and cooked fruit to insure reasonably easy movements. It is not well for the patient to have diarrhea. After about six months the patient is usually able to eat a general diet.

3. Irrigation is advocated every morning after breakfast, the average time for its completion being about one-half hour.

4. Opening of a colostomy is possible through the rectus muscle, but this does not act as a sphincter. There is no objection to bringing it through the rectus muscle. The only criterion of its position is to get it away from the umbilicus and the anterior superior spine.

5. A paste does not need to be used to seal the colostomy. The aluminum paste is used in ileostomies and consists of a mixture of aluminum powder with wool fat. Aluminum powder alone is often dusted around the ileostomy.

6. Loose stools can be controlled by a decrease of fruit and vegetables and the administration of some powders consisting of

15 grains (1 Gm.) of calcium and bismuth subcarbonate. If there is too much flatus, the patient's diet should be somewhat restricted in carbohydrates. Fecal odor is not present if the enema is carried out properly, because there is no discharge from the bowel for twenty-four hours after it has been once emptied.

7. Colostomy cups are difficult to keep clean and free from odor. The patient may be advised to surround the colostomy with a circle of petrolatum gauze, to put a gauze pad over this and then pull up over his abdomen a cheap elastic belt which can be laundered. This combination is effective and hygienic.

UTERINE BLEEDING

To the Editor:—A white woman, unmarried, aged 24, 5 feet 8 inches (173 cm.) tall, weighing 135 pounds (61.2 Kg.), had uterine bleeding daily in varying amounts for four years. The onset of this bleeding occurred following her mother's death. The patient believes that she suffered some nervous shock as the result. During the four years she has had a variety of glandular treatments, mainly injectable materials. Several capable gynecologists have treated the patient for periods of six months or more during her illness. At no time have there been cramps or severe hemorrhage. She has been entirely unable to determine periods. There has been no loss of weight nor any other apparent physical disability. Physical examination has revealed nothing unusual. Pelvic examination is apparently negative. Treatment previous to my seeing the patient has included a dilation and curettement without results. Even radium insertions were tried without success. Since she has been under my care whole ovarian substance, gonadogen (Upjohn) and corpus luteum have been used without success. This patient has become discouraged to the point that she desires a hysterectomy. Can you suggest some way of preventing this catastrophe?

Alfred Breuer, M.D., Cleveland.

ANSWER:—Before hysterectomy is resorted to, two medications should be tried. The first is thyrioid. One or more basal metabolism studies should be made to rule out hyperthyroidism before thyroid therapy is begun. At least one month's trial with thyrioid should be given. One grain (0.065 Gm.) should be taken daily for a week and if untoward symptoms do not arise, 2 grains (0.13 Gm.) should be taken daily. If this treatment does not check the bleeding, the male hormone testosterone propionate may be administered. This patient may be given relatively large doses; 25 mg. of testosterone propionate may be given hypodermically three times a week for four weeks. If the bleeding stops, further medication need not be given unless the irregular bleeding returns. If the bleeding continues in spite of the twelve injections, from six to twelve more injections may be administered, the same dosage being given. When more than 450 mg. of testosterone propionate is given there is some likelihood that signs of virilism will appear. These are growth of hair on the face, lowering of the pitch of the voice and slight enlargement of the clitoris. There is also the strong possibility of a gain in weight and the development of an acneform eruption. However, all these signs disappear after the medication is stopped.

Since testosterone propionate therapy is usually of temporary benefit, the administration of this hormone will most likely have to be repeated from time to time. However, in some cases, for some as yet unexplained reason, normal menstruation often returns after this form of therapy.

GONORRHEAL SALPINGITIS

To the Editor:—A married woman aged 21 has had gonorrheal salpingitis for the past nine months. Two other physicians besides myself have advised removal. She and her parents, who are intelligent, are much opposed to any operation. I am therefore writing for advice as to whether there is any treatment which will offer her a cure without the operation. The patient is in fairly good general condition, only slightly anemic and undernourished. Pelvic examination reveals involvement of both tubes, but it has not extended beyond as far as can be determined. An osteopath has guaranteed a cure by giving her electrical treatments of some type. Unless we can offer her some hope of a cure without an operation she will undoubtedly take these treatments.

G. H. Moronville, M.D., Winton, Wya.

ANSWER:—Eighty-five per cent of patients who suffer from a first attack of gonorrheal salpingitis progress to clinical recovery without recourse to operation. The first measure of importance is to make certain that the patient is not exposed to reinfection, for recurrent infections are more stubbornly resistant to treatment. All sex life should be avoided during the active stage; later indulgence should be limited, and always with condom protection. Rest in bed, care of the bowels, control of pain with codeine and employment of Priessnitz dressings if discomfort is great will usually result in ultimate recovery. Elliott treatments are helpful after the most acute stage, but they are not the cure-all which many have assumed. Sulfanilamide medication is not to be depended on implicitly, yet it is often successful and should be given a trial in all severe cases.

MILROY'S DISEASE

To the Editor:—Two sisters, aged 31 and 36 respectively, have Milroy's disease. Their symptoms began several years ago, at which time they developed painless swelling of both lower extremities. The edema is of the pitting type and extends up to the knees. The older of the two now has swelling of both legs resembling elephantiasis, but no other symptoms. The basal metabolism is normal and results of blood and kidney studies are normal. The younger sister has developed erythematous plaques at the flexor surfaces of both elbows, knees and thighs. She also complains of pains between the shoulder blades. Any information regarding the treatment of this condition will be appreciated.

P. E. Schwartz, M.D., Portland, Conn.

ANSWER:—There is no treatment that will accomplish a cure in Milroy's disease. Various surgical procedures, administration of thyroid and other endocrine substances, and diets have all been tried and have failed. It has been found that rest in bed will decrease the edema and that mechanical relief may be obtained by the application of tight bandages to the lower extremities. Such bandages have been worn for many years by patients with this disease. The condition is not incompatible with long life and good health apart from the mechanical discomfort and the unesthetic appearance.

It seems unlikely that the pain described in this case is a direct result of the disease. Occasionally the skin undergoes changes due to pressure and stretching. Such changes must be treated symptomatically.

GENTIAN VIOLET AND BORIC ACID OINTMENT FOR BURNS

To the Editor:—Will you please supply information on the use of boric acid ointment after aqueous gentian violet has been used in the treatment of burns. It has been brought to my attention that these two preparations are incompatible. If so, please give reasons.

R. W. Bourke, M.D., East Walpole, Mass.

ANSWER:—Gentian violet is usually used relatively soon after the patient has suffered a burn. It becomes fixed by the tissues and forms a superficial crust. After the removal or separation of this crust various substances are used depending on the condition of the tissues underneath the crust. This condition is dependent, of course, on the depth of the burn. Boric acid ointment, if it is used, would be applied after such separation has occurred or after fixation of the gentian violet by the tissues. Even were it to be used early, that is, soon after the gentian violet has been applied, chemical incompatibility which would have a detrimental effect has not been determined.

ALMOND OIL

To the Editor:—Is there any known medical use for sweet almond oil? Can it be safely used as a laxative? If so, in what dosage? The almond is one of the oldest nuts known to man and has been cultivated for thousands of years. Is there any evidence that it was used for medical purposes in ancient times? Some of my friends claim that they have found the almond, and almond oil, of value in arthritis. Is there any basis to their claims? Would its high vitamin and protein content make it of value in preparation of candy for children?

M.D., California.

ANSWER:—Sweet almond oil possesses the emollient properties of the other fixed oils so that it could be used to soften chapped hands and for other inflamed conditions of the skin. It is also useful for the emulsification of volatile oils, as a base. There is little or nothing on which to base a claim of efficacy in cases of arthritis. The oil can be used as a safe laxative in doses of from 4 to 8 cc. The nut should be good for making candy but would be no better than other nuts.

DUODENAL INSUFFLATION OF OXYGEN FOR INTESTINAL DISTENTION IN PNEUMONIA

To the Editor:—Have high concentrations of oxygen instilled directly into the duodenum through a Levine tube ever been used as a method of treatment of patients with pneumonia complicated by a marked distention which has failed to respond to the ordinary methods of treatment of distention, such as stipes, enemas, rectal tube, medication and the like? Would you give me references to any articles on this subject?

Bernard E. Cohler, M.D., Chicago.

ANSWER:—No one seems to have proposed duodenal insufflation of oxygen in the treatment of intestinal distention in pneumonia. This might be a dangerous procedure. Distentions in pneumonia should be classified as those involving the left upper quadrant of the abdomen or stomach and those involving the intestine and colon. The former are relieved by aspiration through a Levine tube or by Wangenstein's suction device. In the intestine they are usually an expression of profound poisoning and are frequently associated with bacteremia. Unless the infection is overcome they are ultimately uncontrollable.

Jacob Fine and his co-workers, who introduced the oxygen inhalation therapy of postoperative distentions, have shown, in several valuable contributions, the mechanism by which this is accomplished (Fine, Jacob; Frehling, Stanley, and Starr, Arnold: Experimental Observations on the Effect of 95 Per Cent Oxygen on the Absorption of Air from the Body Tissues, *J. Thoracic Surg.* 4:635 [Aug.] 1935. Fine, Jacob; Banks, B. M., and Hermanson, Louis: The Treatment of Gaseous Distention of the Intestine by the Inhalation of 95 Per Cent Oxygen, *Ann. Surg.* 103:375 [March] 1936. Fine, Jacob; Sears, J. B., and Banks, B. M.: The Effect of Oxygen Inhalation on Gaseous Distention of the Stomach and the Small Intestine, *Am. J. Digest. Dis. & Nutrition* 2:361 [Aug.] 1935). Inhalation oxygen therapy in pneumonia, which increases the oxygen in the respiratory and gastrointestinal tracts, lessens the incidence of distention. With the prompt and efficient use of chemotherapy and serum therapy abdominal distention is encountered much less frequently than formerly.

SEROLOGICALLY NEGATIVE SYPHILIS AND PREGNANCY

To the Editor:—A woman aged 28 states that she and her husband were treated for syphilis in 1933. They received only about four months of treatment and were discharged. In 1938 the husband's Wassermann reaction was four plus and I gave him two years of continuous treatment, after which it was still four plus and I considered him Wassermann fast. The wife's blood and spinal fluid have been negative on six examinations at intervals of two months. At present the woman is about eleven weeks pregnant; Wassermann, Kahn and Kline reactions are negative; the husband was considered Wassermann fast seven months ago—should I give her any treatment? I did not obtain a positive blood test on her and complete physical examination is essentially negative.

M.D., Missouri.

ANSWER.—Comment is not made in regard to the status of the husband's spinal fluid. It seems unwise to consider him Wassermann fast without knowing the status of the spinal fluid. The fact that the wife's serologic reactions have been repeatedly negative during the past year is not sufficient evidence to discard the need for treatment if she is now in the early phase of pregnancy. Studies have shown slightly less than 20 per cent of women with latent syphilis and who have a negative serologic reaction develop complications as a result of the syphilis during a pregnancy. In other words, it appears advisable to urge this woman to undergo a course of treatment as a means of doing all within her power to have a normal child.

RED CELL VOLUME MEASUREMENTS

To the Editor:—I desire to do red cell volume measurements using either the Sanford and Magath centrifuge tube or the Wintrobe hematocrit tube. If the Wintrobe tube is satisfactory for the combined determination of the sedimentation of velocity and the volumes of the packed red cells I should prefer the Wintrobe tube. Will you advise me whether the Wintrobe tube is sufficiently rugged so there is little or no breakage in the centrifuge? Are the cell volumes as determined by this tube considered accurate? How many times gravity must the centrifugal force be in order to secure reliable volumes in from thirty to sixty minutes' centrifuging time? What is the lowest priced centrifuge which would give satisfactory determination (with an alternating electric current of 110 volts)? Would you advise me also as to the dealer from whom such a centrifuge may be obtained? The equipment is wanted for a small laboratory where the volume of work is not heavy. It is proposed to use this centrifuge only for the red cell volume determination.

Thomas P. Hoslam, M.D., Council Grove, Kan.

ANSWER.—Accurate red cell volume measurements are obtained with both Sanford-Magath and Wintrobe hematocrit tubes. The cell volume varies slightly with the anticoagulant, the centrifugal force and the time of centrifugation. An isotonic anticoagulant (1 cc. of a 1.4 per cent sodium oxalate solution to 5 cc. of blood) is employed with the Sanford-Magath tube. The small Wintrobe tube requires a dry anticoagulant. If heparin or a dry oxalate mixture is used, the readings with the Wintrobe and the Sanford-Magath tubes are the same. The dry anticoagulant is made as follows: Three Gm. of ammonium oxalate and 2 Gm. of potassium oxalate are dissolved in 100 cc. of distilled water; 0.08 cc. of this solution is run into a test tube and dried completely. Exactly 2 cc. of blood is added and mixed. The Wintrobe tube is filled with this oxalated blood. The cells shrink if potassium oxalate only is used, so the reading is multiplied by 1.08. The Wintrobe tube can be used for the sedimentation rate also and is quite rugged.

Any centrifuge is satisfactory if properly calibrated. The small clinical centrifuges obtainable from any laboratory supply house for about \$35 give good results. The blood is usually spun at 3,000 revolutions per minute for from thirty to sixty minutes.

The best procedure is for each laboratory to determine the mean cell volume in normal persons with the technic employed. To find this, determinations on ten obviously normal individuals are done and the normal mean is calculated. The reading for any abnormal blood is compared with this normal value.

INCISIONAL HERNIA

To the Editor:—A patient was operated on in 1924 for appendicitis through a right rectus incision. Recently the patient noticed a small swelling in the scar while straining at stool. There was no pain at the time and the only occasion that the patient can remember having a definite pain in the scar was six months previously when there was moderate pain for a few minutes while lifting a weight of about 75 pounds. Is it probable that breaking of the scar occurred six months previous to the appearance of the hernia or that it occurred without any pain a few days before being noticed?

G. E. Perkins, M.D., Norfon, Va.

ANSWER.—Usually an incisional hernia develops gradually as the result of the many different traumas from strain and exercise in daily activity. It is gradually enlarged. It is not improbable that one heavy lift six months previous to its being noticed has been a stronger factor than the other traumas, but it would be difficult to prove this, perhaps impossible.

CYSTINE-RICH PROTEINS IN TISSUES

To the Editor:—Kindly advise me what polymeric polysulfides are found in the human body.

G. W. Tyrrell, M.D., Perth Amboy, N. J.

ANSWER.—There are no "polymeric polysulfides" found in the human body in the strict sense of the term. The substances which might possibly be classified as near to "polymeric polysulfides" are those proteins which are rich in cystine. Cystine is a disulfide and proteins contain various amounts of cystine. Hair, skin, finger nails and toe nails are particularly rich in cystine as compared with other tissues.

TONSILLECTOMIES IN DIONNE QUINTUPLETS

To the Editor:—The query regarding the justification of tonsillectomies in the Dionne children (*The Journal*, August 10, p. 476) emphasizes a practice which seems to me overdue. Under the circumstances described, Dr. Drafée could hardly have proceeded otherwise than he did. Repeated attacks of acute tonsillitis and swelling of the cervical lymph nodes seem to be the only important indications for tonsillectomy. The opinion of the consultant that there "is palpable evidence that the infection from their tonsils is spreading and at any time may get into the whole system, producing disastrous results . . ." is hypothetical. Such unguarded statements of direct responsibility for dire consequences "unless their tonsils and adenoids are removed at once" have no doubt been responsible for what is called "wholesale tonsillectomy" by the New York physician who questioned the procedure. The quintuplets are at the age when "normal" hypertrophy of lymphoid tissue is present, so that "very large" tonsils or the fact that they "nearly touch each other" may not be abnormal. Many studies referred to in recent papers by Dr. Havens and myself (*Focal Infection and Systemic Disease: A Critical Appraisal*, *The Journal*, Jan. 6, 1940, p. 1; *Infectious Diseases: Review of Significant Studies in 1939-1940*, *Arch. Int. Med.*, August 1940) support our opinion that tonsillectomy performed in children for such supposed dangers is not justified and that large numbers of persons who have tonsils are no worse off than similar groups who have not. Although no figures are available, it would also seem that the risk of serious complications resulting from the operation itself is about as great as the probabilities mentioned in the consultant's opinion.

Hobart A. Reimann, M.D., Philadelphia.

REACTIONS TO SACRAL ANESTHESIA

To the Editor:—In the *Journal* for July 27, page 322, there appears an inquiry concerning "reactions to sacral anesthesia and pernicious anemia." The interrogator stated that "sacral anesthesia" was performed in the case in question. The reply is based on the presumption that spinal anesthesia had been performed. The term "sacral anesthesia," as conventionally used, certainly does not apply to the method of subarachnoid injection. It implies the use of technics for producing regional anesthesia by any one of the various extradural approaches, such as transsacral, presacral or caudal methods. Presumably it was by some extradural method that the interrogator produced anesthesia in the case in question, and it was to learn whether such an anesthetic procedure is capable of causing degeneration of the spinal cord that he made his inquiry. The reply to the inquiry failed to give any information regarding the significant point involved, the incidence of subarachnoid lesions due to extradural injections of anesthetic agents, and furthermore it seems an inadequate statement as to the incidence of neurologic sequelae of spinal anesthesia. Is it possible to say without qualification, for example, that any administration of spinal anesthesia "may be followed by . . . degenerative lesions of the spinal cord"? Such a statement fails to discriminate between the toxic or traumatic factors which are present in certain particular instances and the inherent factors of subarachnoid anesthesia itself. In illustration, it would not be fair to state that "any administration of nitrous oxide may be followed by degenerative lesions of the cortex," since such lesions occur as sequelae of the misuse rather than the correct use of the agent under discussion.

Book Notices

The Soldier's Heart and the Effort Syndrome. By Sir Thomas Lewis, C.B.E., F.R.S., M.D., Physician University College Hospital, London. Second edition. Cloth. Price, 8s. 6d. Pp. 103. London: Shaw & Sons, Ltd., 1940.

This book was published shortly before the close of the war of 1914-1918. In his introduction to the present edition the author states that "the magnitude of the problems presented by this condition from the standpoint of army wastage, invalidism and pensioning will be realized when it is known that not less than 70,000 soldiers had reported sick and were classed as cardiovascular by the summer of 1918; and 44,000 cases of 'effort syndrome' became pensioners. Actually no more than one out of six of these soldiers suffered from disease of the heart. The rest were effort syndrome cases. The problem is the same in this war as in the last; and if this war continues as the last did, it will not be of much less magnitude than it was in that." Lewis proposed the term "effort syndrome" to replace that of "disturbed action of the heart." The new term was to be used to express a group of symptoms and signs which resemble those of physiologic fatigue following exercise in the absence of a definite disease of the heart, lungs or thyroid. The etiology of the effort syndrome, or neurocirculatory asthenia, as physicians in the United States prefer to call it, has never been clearly elucidated. In discussing the contributing etiologic factors he mentions that 57 per cent of the soldiers invalided for this cause were recruited from sedentary or light occupations. Many of these men showed defective physical development and frequently a defective nervous organization. Among the exciting factors Lewis stresses those of strains of training and service. It appears that infection is an important element. Among the British soldiers rheumatic fever was of the greatest importance. Other infections were pneumonia, pleurisy, influenza, bronchitis and dysentery. Infectious diseases, the author estimates, have played a chief part in promoting the syndrome in at least 50 to 60 per cent of the cases. Lewis dismisses the question of "heart strain" by stating "neither in civilian nor in military practice have I seen a patient in whom the evidence for heart strain as a primary cause of breathlessness could be regarded at all convincing." Few soldiers dated the first onset of symptoms to an unusual strain. Such a history was obtained in only five of 558 cases. X-ray studies showed the heart to be on the average smaller than normal. Tobacco, alcohol and venereal diseases played an insignificant part in the causation of the effort syndrome. The most important problem confronting the medical personnel in sorting cardiovascular cases is to differentiate effort syndrome from organic heart disease. Cardiologists will be particularly interested in the chapter on diagnosis of disease of the heart in soldiers. In the author's experience murmurs are to be heard over the precordium in more than half of the soldiers sent to military hospitals for actual or supposed cardiac disorders. The most frequent of these is the cardiorespiratory murmur, which is really a breath sound accompanying a cardiac systole. It is usually associated with a rapid heart action and has no diagnostic or prognostic significance. The author also warns against attaching significance to the pulmonary systolic murmur heard over the second or third left cartilages. On the other hand a palpable thrill and cyanosis suggest the probability of pulmonary stenosis or patent ductus arteriosus. Aortic systolic murmur is of no significance. Diagnosis of mitral regurgitation is justified in the presence of a systolic murmur and a history of rheumatic fever. Rheumatic fever and chorea were responsible for 54 per cent of cases of aortic regurgitation and of 65 per cent of mitral stenosis. There is a valuable chapter on examination of recruits and on medical reports on discharged soldiers.

The author apparently does not regard this interesting syndrome as a primary cardiac condition. He feels that abnormal anxiety must be regarded as a real and important contributing cause. In discussing the treatment he emphasizes that understanding of the relations between nervous states and effort syndrome is essential to successful treatment and deserves further and careful study. The most important contribution by the author to this subject is the method of treating these soldiers by graded exercises. These consist of drills or games so graded that no man is submitted to severe exercises before his tolerance

is thoroughly established. The method is useful for both sorting trained soldiers for work or duty and as specific therapy. Under this method of treatment the hospital stay of patients was reduced from the average of 5.3 months to five or six weeks. The enormous experience of Sir Thomas Lewis in the past war together with his background as a noted cardiologist adds particular importance to this monograph.

Artificial Pneumothorax: Its Practical Application in the Treatment of Pulmonary Tuberculosis. Contributions by Saranac Lake Physicians to the Studies of the Trudeau Foundation. Editorial Committee: Edward N. Packard, M.D., John N. Hayes, M.D., and Sidney F. Blanchet, M.D. Foreword by E. B. Baldwin, M.D. Cloth. Price, \$4. Pp. 300, with 85 illustrations. Philadelphia: Lea & Febiger, 1940.

Those interested in collapse therapy are fortunate in having such a logical statement of the broad principles underlying the employment of artificial pneumothorax in the treatment of pulmonary tuberculosis. The historical background is brief but clearly descriptive of what has gone before, and the facts presented serve as a base line from which the operation may intelligently proceed with the assurance of past results.

The chapter on physiology is well presented and supplies the fundamental physiologic phenomena which should be understood by every one who practices or contemplates the practice of pneumothorax. In the chapter on selection of cases, indications and contraindications are briefly but clearly presented. The authors obviously recognize the danger of drawing hard and fast lines with dogmatic recommendations. They frankly state that experience on the part of the operator serves as a valuable supplement to any proposed criteria for the selection of cases. On the whole, this chapter may be accepted as a valuable aid to the experienced operator and a safe guide for the novice. That part of the chapter dealing with nontuberculous disease is logical and conservative, cautiously safeguarding the inexperienced and leaving the experienced operator an open road for careful trial in questionable cases. A more detailed discussion of pneumothorax in ambulatory cases would have been helpful to those who are trying to solve this question. The chapter devoted to the value of the x-rays in artificial pneumothorax should be carefully studied, in that the x-ray observations should be closely linked with the symptoms and signs before decisions are reached and should serve as a guide subsequent to the induction of pneumothorax. Such a study materially aids in the classification and selection of cases. After pneumothorax is induced, the continued use of the x-rays is valuable in determining the results and directing the course of treatment. New developments in the contralateral lung may be observed and complications such as adhesions, pleural effusions, empyema, mediastinal hernia and spontaneous pneumothorax recognized. The importance of the x-rays in artificial pneumothorax is well shown and perhaps the closing statement is warranted: "The x-ray is not the handmaiden but the mistress of therapeutic pneumothorax." The chapter on apparatus will serve as a valuable guide to those who contemplate the use of pneumothorax as a therapeutic measure. The same may be said of the chapter on technic. The authors are to be commended for pointing out the fact that the technic may be perfectly safe while remaining relatively simple. The chapter on accidents during operation offers a brief but ample discussion of the possible accidents, including the troublesome question of gas embolism and pleural shock. The means of recognition and methods of treatment are well presented. A careful study of the remaining chapters reveals the same concise but brief treatment of the various phases of this valuable therapeutic procedure, including the many additional problems arising in the course of its application. The subjects of the remaining chapters are physical signs in artificial pneumothorax, conduct of treatment, pleural complications of artificial pneumothorax, results of treatment of tuberculous empyema, the opposite lung in artificial pneumothorax, bilateral artificial pneumothorax, artificial pneumothorax and the heart, the duration and termination of treatment, the pathology of the tuberculous lung treated by artificial pneumothorax, oleothorax, thoracic surgery in relation to artificial pneumothorax, and results of treatment by artificial pneumothorax.

This work is recommended by its source, and a thorough study of its contents warrants the conclusion that the authors

have sustained the high quality which characterizes the other publications coming from the Saranac group. This publication constitutes a valuable handbook on artificial pneumothorax and it is doubtful whether so much information in concise form is to be found in any other publication.

The Vitamin B₁ Content of Foods in Terms of Crystalline Thiamin. By Lela E. Booher, Senior Nutrition Chemist, and Eva R. Hartzler, Junior Chemist, Foods and Nutrition Division, Bureau of Home Economics, United States Department of Agriculture Technical Bulletin No. 707. Paper. Price, 5 cents. Pp. 20. Washington, D. C.: Supt. of Doc., Government Printing Office, 1939.

This valuable bulletin gives the vitamin B₁ content of some 100 foods commonly included in the American dietary in terms of international units and micrograms per hundred grams of food (edible portion). This compilation of data is especially useful since the vitamin B₁ content of foods reported in the earlier literature was often expressed in units not always convertible to international units. The daily requirement of a normal adult for vitamin B₁ is considered to be about 400 international units. From this bulletin one can learn which foods are excellent, good, fair or poor sources of vitamin B₁ and select a diet accordingly. Foods listed in the class "excellent" providing no less than 150 international units of vitamin B₁ per hundred grams are dried lima beans, cow peas, rolled oats, peanuts, pork chop (lean portion), smoked ham and soybeans. Foods listed in the class "good," providing from 100 to 150 international units of vitamin B₁ per hundred grams, are fresh lima beans, dried navy beans, egg yolk, dried milk, peas, walnuts and whole wheat. Foods listed in the class "fair," providing from 30 to 100 international units of vitamin B₁ per hundred grams, are asparagus, beef (the lean portion), broccoli, brussels sprouts, cauliflower, chicken (dark meat), corn meal (yellow), corn (sweet), kale, lamb (lean portion), liver, mustard greens, okra, peanuts (roasted), pineapple, potatoes, prunes (dried), spinach, sweet potatoes, turnip greens and wheat (shredded).

Fortschritte der Allergielehre (Forschung und Klinik). Unter Mitwirkung von G. Dahlberg et al. Herausgegeben von P. Kallós. Cloth. Price, \$10. Pp. 400, with 38 illustrations. New York: Nordemann Publishing Company, Inc.; Basel: S. Karger, 1939.

Although the attempt to summarize the recent advances of allergy and immunology in all the fields of medicine is a commendable endeavor, this work is somewhat confusing, owing to the fact that each chapter is written by a different person. Many of the chapters conform to the philosophic flights of fancy one has learned to expect of German "armchair" scientists. The chapter by Haurowitz is excellent and summarizes all the recent work on antigens, antibodies and antigen-antibody reactions. It is worth the price of the book to one interested in this field. Harley's method of treating hay fever may be applicable to conditions in England but would be a failure if adapted to the treatment of ragweed pollinosis as it occurs in the United States. Lowenstein's chapter on allergic diseases in ophthalmology is good. The book is full of the names of foreign proprietaries, the use of which the authors advise. It is much too difficult to remember these names and the reviewer, for one, prefers to use simple pharmacopoeial preparations. We cannot agree with Unditz (who authored the chapter on "Pharmakotherapie") that calcium is practically the cure-all for allergic diseases. One thing that this book illustrates is that allergy has involved every branch of medicine and has succeeded in explaining many previously unclear and perplexing phenomena.

Family Allowances: Children Must Be Fed. Paper. Price, 3d. Pp. 32, with illustrations. Aylesbury, Buckinghamshire: Lancet, 1940.

The fact that "in England today there are children going so short of proper food that their health and growth are being damaged" leads the London *Lancet* to believe that a medical problem is created. Wages are paid on the theory that a man is entitled to "at least a 'living wage'" to cover a "normal family" with three children. But only 3.9 per cent of men have more than three children and these are responsible for 23 per cent of the children. The present so-called living wage does not afford adequate food for a family of even five and is very inadequate for additional children. Since the first item of economy in the family budget is usually food, a large amount of malnutrition results which affects not only the children but

even more frequently the mother and is reflected in a high maternal death rate. The *Lancet* therefore urges a family allowance based on the number of children in the family. Tentative movements in Great Britain and in France, Belgium, Germany, New South Wales and New Zealand provide allowances for the support of children. Three ways of paying such allowances universally have been tried; the whole burden may be put on the employers or on taxation or through a contributory scheme in which employers, workers and the state share. So far from believing that a state of war is an objection to undertaking such a plan, it is urged that "now is the time to prevent the onset of widespread poverty, with all the nutritional disasters which it creates."

Practical Food Inspection. By C. R. A. Martin, M.R.San.I., Chief Sanitary Inspector, Whitstable. In Two Volumes. Volume I: Meat Inspection. Volume II: Fish, Poultry and Other Foods. Second edition. Cloth. Price, 15s.; 12s. 6d. Pp. 316, with 138 illustrations by the author; 275, with 58 illustrations by the author. London: H. K. Lewis & Co., Ltd., 1940.

These two volumes are by a practical inspector who makes excellent use of "data collected during routine inspectorial work extending over a period of many years." The first edition (November 1932) was apparently well received and made this revision with the introduction of new material necessary. This work contains information valuable not only to the inspector with scientific training but also to those without that background, as it does not include highly technical details. The first volume, on meat inspection, is thorough and well done. It does not attempt comprehensive coverage of physiology or anatomy, and the material on antemortem inspection is limited but all the information given is of fundamental importance. The suggestions as to a system of meat inspection could well be carefully considered for adaptation to intrastate meat by state and municipal officials to supplement federal meat inspection of interstate meat. The sections on diseases and pathologic abnormalities are well done from the standpoint of the meat inspector and the procedure followed of defining the condition or disease, stating the etiology, giving the postmortem appearances and finally and in definite terms rendering "judgment" is particularly convenient for inspectors. The second volume covers fish and poultry briefly. The lack of detail is somewhat surprising for a country which consumes the amount of fish that Great Britain does. But even more briefly are "other foods" covered, which clearly reveals the author's primary interest in meat inspection. Perhaps this is judging from the standpoint of American industry and when, for example, the size of the British canning industry is considered it is not so surprising that only eleven pages is devoted to it. Each volume contains a short glossary of terms and an index.

Clinical Toxicology. By Clinton H. Thienes, M.D., Ph.D., Professor of Pharmacology and Head of the Department of Pharmacology, School of Medicine, University of Southern California, Los Angeles. Fabrikoid Price, \$3.50. Pp. 309, with 7 illustrations. Philadelphia: Lea & Febiger, 1940.

As stated in the preface, the author's purpose in writing this book was to provide a classroom textbook and a guide for the general medical practitioner. No attempt has been made to discuss in detail the chemistry, pharmacy or general pharmacology of poisons. The author has departed from the usual scheme of classifying poisons according to their chemical composition and has grouped them according to their mechanism of action or chief presenting symptom. From the standpoint of classroom instruction, such a system appears to be more satisfactory than classification on the basis of chemical behavior. It is not without imperfections, however. Thus one finds phenol discussed under three separate categories: as a corrosive poison, as a convulsant and as a kidney poison. Atropine is listed both as a cerebral convulsant and as a nerve depressant. Such subdivision, although pharmacologically accurate, might prove to be just as confusing to the student as are the incongruities resulting from the chemical classification of poisons. The consideration of the toxicology of specific poisons, which occupies three fourths of the book, is treated in a clear and concise manner. Discussions of diagnosis and specific treatment are reasonably adequate. One might disagree with the author concerning the relative importance of certain toxic agents. Thus it seems difficult to justify the space given to

considerations of poisoning by absinthie, curare, histamine, poke root and phenylhydrazine in view of the omission of more common poisons such as the newer chlorinated solvents (trichloroethylene, tetrachlorethylene, ethylene dichloride), sulfur dioxide, carbon dioxide, chlorine gas, formaldehyde, santonin, potassium permanganate and metals such as antimony, cadmium, copper and silver. The student or physician who desires additional information beyond that provided in this elementary textbook will be disappointed by the author's failure to cite references to the sources of his information. The last fourth of the book is concerned with general principles for the treatment of poisonings, with diagnosis of poisoning according to the symptoms produced and with chemical technics for the detection and estimation of poisons. The analytic methods given are mostly elementary qualitative procedures and, while quite satisfactory for purposes of class instruction, are hardly adequate for clinical diagnostic use. In a recent review of another manual of toxicology, Prof. H. C. Wood aptly remarked that we were apparently experiencing an epidemic of "toxicologitis." Of the four books on the subject which have been published in this country during the past year, this one is probably the most satisfactory for its intended purpose of providing a brief textbook for medical students and clinicians.

Pathologisch-physiologische Grundlagen der Chirurgie. I: Der Stütz- und Bewegungsapparat. Knochengerüst, Gelenke, Muskeln, Sehnen, Sehnensehiden und Schleimbeutel. Von Dozent Dr. med. habil. Herbert Junghans, Oberarzt der Chirurgischen Klinik und der Poliklinik der Universität Frankfurt a. Main. II: Harn- und männliche Geschlechtsorgane. Von Dozent Dr. med. habil. Ernst Kraas. III: Darm und Bauchfell. Von Prof. Dr. Victor Orator, Chefarzt am Stadtkrankenhaus Duisburg. Paper. Price, 9.60 marks; 4.20 marks; 8 marks. Pp. 118; 46; 92, with 8 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

This monograph is in general well organized and written. The field is well covered, though several topics could be included with benefit; e. g., bone tumors are not discussed. The author includes some original work, observations and ideas, and presents problems which bear further research work. The bibliography is large, but there are several glaring omissions.

Part II is well written but in many places incomplete. It is brief, to the point and well subdivided, but the many omissions keep it from being a good monograph. The kidney in relation to hypertension (Goldblatt kidney) is not mentioned. The entire chapter on the male sex organs is only two and a half pages long. The innervation of these organs is not mentioned. The endocrine aspects of prostatic hypertrophy are not discussed. Among other subjects missing are hermaphroditism and eunuchoidism.

Part III is the least well written of the three monographs. The German is difficult to read, the punctuation is poor and there are many typographic errors. While some normal physiologic processes of digestion are thoroughly discussed, there are so many subjects omitted that the book is hardly worth the time taken to read it.

Treatment of War Wounds and Fractures with Special Reference to the Closed Method as Used in the War in Spain. By J. Trueta, M.D. With a foreword by H. Winnett Orr, M.D., F.A.C.S. Cloth. Price, \$2.50. Pp. 146, with 48 illustrations. New York: Paul B. Hoeber, Inc., 1940.

Dr. Trueta reports on the use of closed plaster casts in the treatment of war wounds. He believes that the principal value of the cast is the immobilization which it affords. This allows local venous and capillary thrombi to form which prevent and delay the spread of infection and allow new capillaries to form. Repeated dressings break these down. The plaster maintains a constant beneficial pressure on the wound. He believes that biologic antagonism between the different groups of bacteria renders impossible the colonization of pyogenic organisms and so slows up the septic process. He found *Bacillus pyocyaneus* in abundance in a number of cases. The immediate care of the wounds is the most important part of the treatment. The steps included are anesthesia, débridement, reduction of the fracture, light packing of the wound with gauze (not with petrolatum as advocated by Dr. Orr) and prophylactic tetanus antitoxin. Then the cast is applied and changed only if the odor becomes unbearable. Failures, he believes, result from inadequate surgical management of the wound before the cast is applied. Special problems in the various regions are discussed. Advantages of the method peculiar to military surgery include the ease of

arranging early care and transportation and the small amount of equipment and after-care needed. The treatment of 1,073 compound war fractures with mortality in only six cases is proof of the ability of the author and the soundness of his method.

Clinical and Experimental Investigations on the Creatine Metabolism. By Erling Waag. *Acta medica Scandinavica*, Supplementum CV. Paper. Pp. 338, with 38 illustrations. Helsingfors: Mercators Tryckeri, 1939.

This monograph, in harmony with others sponsored by the *Acta medica Scandinavica*, permits the author to discuss in some detail the metabolism of creatine on the basis of his own studies and those in the literature. The object of the investigations described was to study the origin and significance of creatinuria and determine whether creatine elimination could be utilized clinically for diagnostic or prognostic purposes. The studies deal largely with creatine metabolism in disturbances of the thyroid gland and in diseases of the muscles but also include studies of creatine-creatinine excretion in such conditions as pernicious anemia (and other blood diseases), uremia, hypertension, heart disease and fever. In thyrotoxicosis the creatinuria was found to be dependent on some action of thyroxine, but this was independent of the basal metabolism. Since creatinuria occurs in a wide variety of conditions, the author concludes that it is an unspecific phenomenon resulting from the general debilitation of the patient and is of clinical value only in judging the extent, severity and course of diseases specifically affecting the muscles. While the author's own studies appear to be well organized and carried to a logical but somewhat detailed conclusion, the discussion of the relatively enormous literature (1,455 references) reveals some inadequacies in the discussion of previous studies bearing on the problem in hand. The book will be found, however, to contain considerable material of interest to students of creatine-creatinine metabolism.

Report of the Chief of the Bureau of Home Economics, 1939. United States Department of Agriculture, Bureau of Home Economics. Paper. Price, 5 cents. Pp. 22. Washington, D. C.: Supt. of Docs., Government Printing Office, 1939.

This annual report of the Bureau of Home Economics for the fiscal year which ended June 30, 1939, is of interest because the Bureau of Home Economics, a division of the United States Department of Agriculture, conducts investigations that further the well-being of all persons in the United States through more effective use of foods and other agricultural products and works toward improving the living of farm families.

The scope of the Bureau's activities includes economic studies on the level of living a family can achieve on a limited income; foods and nutrition studies on the kinds and amounts of essential nutrients required to maintain and promote maximum health; collection of data on the composition of foods; studies of the influence of methods of production and processing on the quality of foods; textile and clothing studies on the chemical and physical properties of various textile fabrics, studies to determine the best quality of fibers and the best fabric construction for particular use, and the development of an improved basis for sizing children's garments and patterns; housing and equipment studies on the minimum space requirements for effective arrangement of needed equipment, work spaces and storage spaces.

Bulletins describing these studies were prepared and published during the year together with articles in outside journals. A list of the publications and articles is provided in this report.

Elements of Human Physiology. By Mirlam Scott Lucas, B.S., Ph.D. Cloth. Price, \$1.50. Pp. 400, with 153 illustrations. Philadelphia: Lea & Febiger, 1940.

This textbook was written for college courses and is based on actual teaching experience. While brief and concise, the scope of subject matter seems well balanced, well integrated and correlated. Some of the illustrations are original, some reproduced from standard sources. There are twenty tables. On the whole, the work seems somewhat superior to most recent college textbooks despite a certain degree of dogmatic presentation. This the author, in the preface, justifies on the ground that controversial subjects should not be stressed too much with the class of students for whom the book is designed. Probably such a view is justified. Certainly no one will be misinformed by any of the material presented.

Chronic Manganese Poisoning in an Ore-Crushing Mill. By Robert H. Flinn, Passed Assistant Surgeon, and others. From the Division of Industrial Hygiene, National Institute of Health. Prepared by direction of the Surgeon General. Federal Security Agency, U. S. Public Health Service. Public Health Bulletin No. 247. Paper. Price, 15 cents. Pp. 77, with illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1940.

Eleven cases of chronic manganese poisoning are reported in this engineering and medical survey of an ore-crushing mill. These observations point out the interesting neurologic manifestations of long-standing manganese intoxication, especially the similarity to such nervous disorders as multiple sclerosis. The distinguishing features are a history of exposure to sufficient concentrations of manganese dust over a long enough time, the appearance of muscular stiffness and incoordination progressing to marked alterations in speech and gait, relative and absolute diminution of neutrophils, lowered blood calcium, and a slight reduction in the middle zone of Lange's test. No cases of chronic poisoning were discovered in exposures of less than 30 mg. of manganese per cubic meter, but caution is expressed not to accept such a figure as a threshold limit. The necropsy in one case demonstrated that the lungs were the principal port of entry and major loci of stored manganese; the liver and kidneys were not found to be greatly changed. Postmortem changes prevented microscopic study of the brain and cord. This report indicates that manganese poisoning is entirely unnecessary and that modern equipment can control the exposure.

Biography of Dr. Joseph Strong 1770-1812, Philadelphia Physician. By Lockwood Barr. Paper. Pp. 43. Pelham Manor, N. Y.: The Author, 1940.

Joseph Strong was born in Connecticut in 1770, studied medicine, practiced in Philadelphia after the Revolutionary War and died in 1812. He is credited with having been the inventor of the tourniquet, and the members of his family who have published this biography are seeking earnestly a specimen of the type of tourniquet he invented so that they may present it to the Yale School of Medicine. In his early days he made some mechanical inventions anticipating the principle of the bicycle. He also obtained a patent on a carriage propeller. He studied medicine in the University of Pennsylvania; although he did not graduate, he attended a course of lectures by Benjamin Rush. Dr. Strong was a member of the group known as the Hartford Wits, whose poems were published in 1793 in an anthology. He was from 1793 onward surgeon in the army in charge of the army hospital 22 miles south of Pittsburgh. The record of his life is an intimate account of an interesting character.

Synopsis of Obstetrics. By Jennings C. Litzberg, M.D., F.A.C.S. Fabrikoid. Price, \$4.50. Pp. 394, with 157 illustrations. St. Louis: C. V. Mosby Company, 1940.

It is difficult to present the subject of obstetrics in outline form, particularly when the size of the book is limited. Nevertheless the author, who has been one of the leading teachers of obstetrics for more than a generation, has skillfully accomplished his purpose. He has arranged the important details of obstetrics in brief and succinct sentences. The treatment recommended by the author is conservative and in accordance with present day teachings. The book is well illustrated but nearly all the illustrations were borrowed from other books. This synopsis should prove helpful to medical students and to general practitioners who want to review various obstetric subjects with a minimum of time and effort.

Unconquered Enemy. By Boris Sokoloff, M.D., Sc.D. Cloth. Price, \$1.75. Pp. 198. New York: Greystone Press, 1940.

This is an extensive and detailed discussion of cancer research by a man who has been in close touch with research scientists all his life. The book is full of useful and interesting information for the cultured person of an inquiring turn of mind who likes his facts with a background of history and embroidered with descriptions of the scientists whose work is cited and of the laboratories in which they labored. The book is too technical for reading by persons of limited education. It contains too much speculative material of interest to the scientist and the seeker after information for its own sake to be of use to the practical individual who wants to know merely what science

has learned about cancer and how such knowledge must be applied definitely to his own situation. In the chapter about the curability of cancer there is much information which will do more to alarm the reader than reassure him, although the conclusions reached are in accord with the general attitude of scientific and clinical observers, namely that there is more hope on the cancer horizon than there has been in previous years. The general style of the book and the inclusion of bibliographic references, largely to the medical literature, are characteristic of the work of the scientist emerging briefly from the cloister of the laboratory to share his precious information with an ignorant public, but not being able to depart wholly from the scientific method of communication. For this reason, unfortunately, this excellent book may have too limited an audience.

Diagnostica differenziale delle emopatie. Di Edoardo Storil. Estratto da "Diagnostica medica differenziale," di Adolfo Ferrata. Paper. Pp. 357, with 79 illustrations. Milan: Cromotipi E. Sormani, 1939.

Here is a monograph on the blood dyscrasias. The first two chapters deal with the genesis and morphology of the various types of blood cells. Two excellent colored charts illustrate all three types of blood cellular elements. The third chapter deals with the anemias. This includes the symptoms, the signs and the hematologic classifications of the anemias. There are in this chapter several colored plates illustrating the various types of anemia, as well as the appearance of the bone marrow in pernicious anemia in a state of relapse. The chapters on the myeloses, the hemorrhagic diseases and the diseases of the lymph glands are complete and well illustrated in color as well as black and white. The chapter on splenomegaly is complete, as is the one on polycythemia. The last chapter illustrates a sternal puncture and a splenic puncture vividly and clearly, as well as a lymph gland puncture. The colored plates of all three of these conditions are excellent. This book is an excellent monograph on the diagnosis and differential diagnosis of the blood dyscrasias, with as fine colored plates of the peripheral blood cells, as well as bone marrow sections, as can be found in any of the textbooks or blood atlases.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Act (Minnesota): Right of Injured Employee to Select Physician at Employer's Expense.—Carmody was injured in the course of his employment with the city of St. Paul. He obtained medical treatment from his family physician and refused to accept the services of any of the physicians designated by the city to treat him. The city paid him compensation during the period of his disability and such hospital expenses as were necessitated by his injuries but refused to pay his physician's bill of \$110. In subsequent proceedings instituted under the workmen's compensation act of Minnesota by Carmody the industrial commission upheld the city, and the workman brought certiorari to the Supreme Court of Minnesota.

The sole question to be determined, said the Supreme Court, is whether or not an injured workman who has been treated by a physician of his own choice can require his employer to pay for the reasonable value of the physician's services when the employer is willing and ready, to the knowledge of the workman, to furnish and pay for medical treatment by a physician of the employer's choice. To determine that question the court regarded it as essential to discuss the legislative history of pertinent provisions of the workmen's compensation act of Minnesota in the light of a prior court decision rendered thereunder. The act originally adopted in 1913 provided

such medical and surgical treatment . . . as may be reasonably required at the time of the injury and thereafter during the disability, but not exceeding ninety (90) days, to cure and relieve from the effects of the injury, the same to be provided by the employer and in case of his inability or refusal seasonably to do so, the employer to be liable for the reasonable expense incurred by or on behalf of the employee in providing

the same; provided, however, that the total liability . . . shall not exceed the sum of one hundred dollars. . . . (Laws, 1913, c. 467, section 18).

In 1921, after study by an interim committee, the section just quoted was amended so as to provide that such medical and surgical treatment

as may reasonably be required at the time of the injury, and during the disability for not exceeding ninety (90) days and not exceeding one hundred (\$100.00) dollars in value, to cure and relieve from the effects of the injury, shall be provided by the employer and in case of his inability or refusal seasonably to do so, the employer shall be liable for the reasonable expense incurred by or on behalf of the employee in providing the same. . . .

The Commission may upon the petition of an employee and a proper showing of cause therefor order a change of physicians and designate a physician suggested by the injured employee or by the Commission itself and in such case the expense thereof shall be borne by the employer [within the limitation just noted]. (Laws, 1921, c. 82, section 19.)

The interim committee in reporting to the Minnesota house of representatives on the bill, which on its enactment became the law just quoted, stated: "This provision [referring to the paragraph of quoted matter which authorized a change of physicians on the petition of an employee] is intended to overcome the objection to permitting the employer to select any physician and require the employee to accept him."

In *Lading v. City of Duluth*, 153 Minn. 464, 190 N. W. 981, a case involving facts similar to those in the instant case and decided while the workmen's compensation act as amended in 1921 was still in force, this court held that Lading, an injured employee of the city of Duluth, could not recover the reasonable value of the services rendered by a physician of his own choice because it had not been shown either that the employer was unable to furnish a physician or that he had refused to do so. However, in holding that the employer was liable to reimburse Lading to the extent of \$100, the statutory limit at that time, this court said:

But we are of opinion that the statute should not be construed to impose upon the employee the unqualified obligation to accept the physician selected by the employer, or forfeit the right of reimbursement there given. It often happens, a situation perhaps more or less general, that the employee has a family physician to whom he prefers to turn in case of injury or sickness, rather than to accept the services of another with whom he has no acquaintance, or in whom perchance he has no confidence. In that situation he should have the option or unquestioned right to choose his medical attendant, or accept the one tendered him by the employer, but within the limits of liability on the part of the employer imposed by the statute. The statute contains no language unconditionally requiring the latter to accept the physician tendered him or relinquish the right of reimbursement altogether, and we construe it to give him that option. . . .

Undoubtedly, continued the court, the construction adopted by us in the Lading case diametrically opposed the purpose of the lawmakers, as evidenced in the report of the interim committee, to vest in the employer in the first instance the right to designate the physician to treat a workman who had sustained an industrial injury. However, the court was of the opinion that the rule announced in the Lading decision should not now be altered in view of the fact that the legislature, which was aware of the holding in that case, had made no subsequent attempt to amend the pertinent provisions of the compensation act relating to choice of a physician. This legislative inaction, the court held, constituted acceptance by the legislature of the statutory construction laid down in the Lading case. In 1923 the legislature again amended the provisions in question without altering the respective fundamental rights and duties of employer and employee except that the financial limit on the employer's liability was removed and the employer was also given the right to apply for a change of physicians. Manifestly, said the court, the 1923 legislature, if it had not intended to adopt the construction placed on these provisions by the Lading decision, could have specifically provided, which it did not, that the employer could designate a physician whose services the employee must accept or forfeit any claim against the employer for services rendered by a physician of his own choice. Again in 1929 the legislature reenacted the provisions in question of the 1923 law except that the ninety day limit was eliminated. Consequently, despite repeated opportunities to alter the rule of the Lading case, the legislature has not done so. Inasmuch as the holding in the Lading decision had become a part of the compensation law, since it had, in effect, been adopted by the

legislature, the court was unwilling at this late stage to reexamine that decision to determine its soundness or unsoundness, and it believed that any change, if needed, should be made by the legislature.

The court accordingly concluded that the workman should have been awarded the amount claimed for medical services, which amount was stipulated to be reasonable. It therefore reversed the order of the commission denying the workman's claim and remanded the cause with directions to award the workman the money spent by him in employing his own physician.—*Carmody v. City of St. Paul (Minn.)* 291 N. W. 895.

Workmen's Compensation Act (Minnesota): Right of Injured Workman to Change Physicians at Expense of Employer.—Morrell, an employee of the city of Austin, Minn., on Jan. 26, 1935, in the course of his employment suffered "painful and lasting injuries" necessitating his submitting to a herniotomy and to a lumbosacral fusion operation on his spine. Immediately after the accident he was placed under the care of a physician selected by the city and its insurer. Eight months later he was examined by another physician, selected by his employer and its insurer, who reported that Morrell's condition was due to congenital abnormalities not caused by or associated with the industrial accident. Apparently medical attention was discontinued even though the workman continued to suffer and was confined to bed most of the time. In March 1936 Morrell wrote to the industrial commission of Minnesota and asked to be sent to the Mayo Clinic and for advice as to how that could be done free of expense to himself. He received a reply from an attorney for the commission advising him to obtain the authorization of his employer's insurer so as to avoid a dispute later on, since "the employer and insurer under compensation have the exclusive right to appoint the attending physician" if they are to be liable for expenses. The workman communicated with the insurer and was eventually instructed to go to Minneapolis to submit to an operation there by physicians designated by the insurer. He was told that if he went to the Mayo Clinic it would be at his own expense. Nevertheless, he went to that clinic and underwent a herniotomy in May 1936. In April 1937 another operation, described as a "difficult surgical matter, involving as it did a 'lumbosacral fusion' of the spine," was performed at the same clinic. Satisfactory recovery apparently resulted. The workman instituted proceedings under the workmen's compensation act of Minnesota to recover from the employer and its insurer the cost of the medical and hospital services incurred at the clinic. While the commission found that the services rendered at the clinic were given to cure and relieve conditions caused by the industrial injury, it denied the workman's claim because he had made "his own selection and failed to secure the permission of the employer or the insurer herein so to do or to secure from the industrial commission . . . an order for change of physicians." The workman then brought certiorari to the Supreme Court of Minnesota.

The right of the workman, said the Supreme Court, to be reimbursed by the employer and its insurer for the services rendered him at the clinic must be determined in the light of the provisions of the workmen's compensation act relating to the furnishing or supplying of medical care necessary "to cure and relieve from the effects" of an industrial injury. In this respect, 1 Mason Minn. St. 1927, section 4279, provides

[the employer] shall furnish such medical, surgical and hospital treatment, including nursing, medicines, medical and surgical supplies, crutches and apparatus, including artificial members, as may reasonably be required at the time of the injury, and during the disability . . . to cure and relieve from the effects of the injury, provided that in case of his inability or refusal seasonably to do so, the employer shall be liable for the reasonable expense incurred by or on behalf of the employee in providing the same. . . .

The Commission may at any time upon the request of an employee or employer order a change of physicians and designate a physician suggested by the injured employee or by the Commission itself and in such case the expense thereof shall be borne by the employer. . . .

In the opinion of the court, inasmuch as Morrell's employer and its insurer and the physicians selected by them had, for a period of more than sixteen months, fumbled and delayed the discovery and treatment of Morrell's real condition, the conduct of the employer and its insurer constituted, within the meaning of the statute, "inability or refusal seasonably" to furnish necessary

treatment. The section in question, continued the court, authorizes the commission to "order a change of physicians" at any time, but in selecting another physician it must designate either one "suggested by the injured employe" or one of its own choice. While either employer or employee may "request" a change of physicians, only the employee or the commission may "designate" such physician. In the instant case the commission did not "refuse" the workman's request for a change of physicians. However, it erroneously advised the workman to obtain the consent of his employer and its insurer because they had "the exclusive right to appoint the attending physician." In other words, the commission washed its hands of the whole affair and never exercised its granted authority. Its inaction permitted the employer and its insurer to be adamant in erroneously claiming that if the workman did not accept their chosen physicians they would be "compelled to decline to assume any responsibility whatsoever for any expense incurred."

The workman, continued the court, was an ordinary working man wholly uninformed as to procedural requirements and was without aid of counsel. He was left completely ignorant as to the true legal course to pursue to get needed professional aid. He indicated his choice of medical service in language that no one could misunderstand. His own rehabilitation was uppermost in his mind. The wisdom of that choice is apparent from the results obtained. In view of the reasoning adopted by this court in *Carmody v. City of St. Paul*, 207 Minn. 419, 291 N. W. 895 (abstracted on the preceding page), it is clear that the workman is entitled to reimbursement for the medical and hospital expenses incurred and paid by him. However, said the court, if the employer and the insurer had correctly informed the workman of his rights and if he had then ignored them, a different result might now be compelled.

The Supreme Court accordingly reversed the order of the commission denying the workman's claim and instructed the commission to allow the workman reimbursement from the employer and its insurer for the amount of the charges made by the clinic.—*Morrell v. City of Austin et al. (Minn.)*, 293 N. W. 144.

Contraceptives: Unlawful in Connecticut for Physician to Prescribe or Advise Use of Contraceptive Drugs or Devices.—Two physicians, Nelson and Goodrich, prescribed and advised the use of a certain spermaticidal drug and a certain contraceptive device by a married woman who sought their advice. The purpose of advising the use of such drug and device admittedly was to prevent conception, and the patient actually used them for that purpose. Subsequently the two physicians and the trained nurse who carried out their prescription, Clara McTernan, were prosecuted by the state in three separate actions for violation of the statutory law of Connecticut, which provides that any person who shall use any drug, medicinal article or instrument for the purpose of preventing conception, or who shall assist, abet, counsel or cause another to commit such an offense shall be fined or imprisoned or both (General Statutes of Connecticut, 1930, sections 6246 and 6562). The defendants claimed that, since their advice and conduct was necessary to preserve the "general health" of their patient, they had done no wrong. From judgments of the trial court sustaining the defendants' demurrers and holding the defendants not guilty, the state appealed to the Supreme Court of Errors of Connecticut.

The Supreme Court of Errors could not agree with the defendants' contention that either the statutory law in question should be construed so as to include an exception protecting the right of a physician to prescribe contraceptive measures when in his opinion such steps are necessary to preserve the "general health" of his patient or else the statute was unconstitutional. In the judgment of the court the wording of the statute was clear and unambiguous and contained no provision excepting a physician from its terms. Furthermore, no legislative intent to exempt physicians could be implied because at each session from 1923 to 1935 the legislature had rejected bills proposing to amend the statute in question so as to exempt the use of contraceptive drugs and devices on the prescription of a physician and to exempt the sale of such drugs and devices to physicians on their prescriptions. The defendants' contention, that the statute in question was unconstitutional because without due process of

law, it deprived the people of their natural right to decide whether or not they should have children and to use contraceptives if they decided not to have them, likewise did not meet with the court's approval. Under its police power a state may legislate to preserve and protect the public morals and to aid what is sanctioned by usage or held by the prevailing morality to be necessary to the public welfare. It must be assumed, said the court, that at the time the statute was originally enacted the legislature was aware of opposing views concerning contraceptives and that it deliberately chose between them. This is especially true since the legislature has repeatedly refused to modify the statute by amendment. The court believed that it was not for it to say that the legislature might not reasonably hold that artificial limitation of even legitimate child-bearing would be inimical to the public welfare and that the use of contraceptives would be injurious to public morals. In fact, the legislature was not precluded from considering that not all married people are immune from temptation or inclination to extramarital indulgence and that the risk of illegitimate pregnancy is a recognized deterrent deemed desirable in the interests of morality. The court concluded, therefore, that the statute was constitutional. It added, however, that if the statute was unwise or unreasonably comprehensive, the appeal should be to the legislature and not to the court.

Accordingly, the judgments of not guilty were reversed and the causes remanded with instructions that the defendants' demurrers be overruled.—*State v. Nelson; State v. Goodrich; State v. McTernan (Conn.)*, 11 A. (2d) 856.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J. Obstetrics and Gynecology, St. Louis 40:1-180 (July) 1940. Partial Index

- Nutrition Study in Pregnancy: Correlation Between Dietary Survey of Vitamin A Content and Dark Adaptation Time. P. F. Williams, B. Hark and Florence G. Fralin, Philadelphia.—p. 1.
- *Pregnancy Pyelonephritis in Relation to Renal Damage and Hypertension: Clinical Study of Forty-Five Cases of Pyelonephritis More Than Five to Ten Years After Infection. E. G. Crabtree and D. E. Reid, Boston.—p. 17.
- *Erythroblastosis Foetalis: Report of Twenty-Seven Cases. S. A. Wolfe and I. Neigus, Brooklyn.—p. 31.
- Relationship of Thyroid and Adrenal Glands to Toxemias of Pregnancy. E. C. Hughes, Syracuse, N. Y.—p. 48.
- Treatment of Oliguria and Anuria. W. J. Dieckmann and S. Kramer, Chicago.—p. 61.
- Endometrium-like Mucosa Lining the Fallopian Tube: Its Origin, Differential Characteristics and Clinical Significance. A. A. Marchetti, New York.—p. 69.
- Prolapse of Umbilical Cord: Analysis of Fifty-Eight Cases. W. F. Mengert and F. H. Longwell, Iowa City.—p. 79.
- Epidemic Infectious Diarrhea of Newborn Infant. R. S. Cron, H. W. Shutter and A. H. Lahmann, Milwaukee.—p. 88.
- Effect of Thyroid on Sterility in Normal and Hypothyroid Females. L. B. Winkelstein, New York.—p. 94.
- Study of 1,200 Cases of Hysterectomy. P. H. Smith, Evanston, Ill.—p. 118.
- Uterine Bleeding in Last Trimester of Pregnancy: Its Diagnostic Significance and Treatment. J. T. Wallace, New York.—p. 128.
- Suppression of Lactation by Stilbesterol. C. W. Mueckle, Philadelphia.—p. 133.
- Stilbesterol in Treatment of Menopausal Symptoms. F. L. Payne and C. W. Mueckle, Philadelphia.—p. 135.

- Removal of Gräfenberg Ring Without Interruption of Pregnancy. R. A. Kimbrough Jr. and P. Tompkins, Philadelphia.—p. 156.

Pregnancy Pyelonephritis, Renal Damage and Hypertension.—Crabtree and Reid point out that in infections of the urinary tract in pregnancy and in the puerperium there is little evidence in most cases of renal insufficiency and, where such insufficiency has been demonstrated, there is prompt return to normal function. These apparent facts tended to strengthen the view that pyelonephritis is a transitory disorder. Obstetric and urologic practice have been dominated by this point of view to such an extent that preservation of the fetus, even in severe cases of pyelonephritis of pregnancy, has been made paramount unless immediate danger to the mother was indicated. The newer concept of the severity of the remote effects of pregnancy pyelonephritis now threatens a reversal of policy. Some writers are prepared to advocate interruption of pregnancy on evidence which obstetricians consider inadequate. The authors think that, until some of these questions have been answered through clinical study of apparently healthy women who have had the disease, a radical policy of interruption of pregnancy for pyelonephritis is no more logical than a policy which preserves the pregnancy at any cost to the mother short of death. In a survey of forty-five patients with pyelonephritis of pregnancy the authors produce evidence by intravenous pyelography, intravenous phenolsulfonphthalein excretion, concentration of the urine test and tests for nitrogen retention to indicate that a high percentage of patients suffer appreciable damage to their kidneys which is demonstrable at from five to ten years after the infection. For the majority adequate renal function is present at that time. The prognosis is grave for the patient who has had both

toxic and pyelonephritic injury. All three patients who had had both toxemia and pyelonephritis had hypertension. Two of the three were dead five years after the injury. Six patients with pyelonephritis showed blood pressure readings above 150/90, associated with some evidence of renal deficiency at that stage of the disease. Renal damage consisted of injury both to the conduction channels, pelvis and ureter and to the cortex. When there is injury to the conducting channels, urinary stasis may further injure the cortex, especially when infection is still present. Five of the forty-five patients studied had stone. Evidence of total renal deficiency was present at the time of examination in some proved unilateral cases. This suggested some other injury than bacterial invasion for the second kidney. The authors gained the impression that pyelonephritis of pregnancy should be looked on as a progressive disease in many cases. Data have not yet been produced to indicate to what extent it shortens life. Some of the cases which were subnormal may have shown only the original damage and may now be in a stationary state. Sufficient evidence has been produced to indicate that the aim in treatment in pyelonephritis associated with pregnancy should be to minimize the initial injury and clear the infection as soon as possible.

Erythroblastosis Foetalis.—According to Wolfe and Neigus, erythroblastosis foetalis is a disease of the blood-forming organs of the newborn infant, which results in an anemia characterized by the presence of an excessive number of immature red blood cells in the circulation. Hydrops foetalis, icterus gravis neonatorum and anemia haemolytica neonatorum are the three clinical types of erythroblastosis. Overlapping features are not infrequent. Five infants in the icteric group presented circumscribed edema. Icterus was the first symptom in the three infants of the anemia group. Erythroblastosis foetalis is not rare. Twenty-seven cases were encountered in 15,334 deliveries, an incidence of one in every 568 confinements. There were four cases of hydrops foetalis, twenty cases of icterus gravis and three instances of anemia haemolytica. Persisting hematopoiesis in the liver and spleen is the dominant pathologic aspect. The bone marrow is hyperplastic. Extramedullary hematopoiesis is often encountered in the pancreas, kidneys and adrenal glands. The hemoglobin and red cells are reduced but the color index is above standard. The total number of nucleated cells is increased with an abnormally high ratio of early red blood cells (normoblasts and erythroblasts). A tendency for recurrence in successive pregnancies is noteworthy. Four such cases are reported among nineteen mothers of the icteric group. Recurrent stillbirths were observed in 75 per cent of mothers with hydropic children and in 21 per cent of mothers who had delivered icteric progeny. Toxemia of pregnancy is above the normal incidence but of only moderate severity; it was noted in 50 per cent of the hydrops group in 20 per cent of the mothers in the icteric group. Premature labor is frequent; it was encountered in all the hydrops cases and in 30 per cent of the icteric series. In hydrops foetalis the distended abdomen may cause dystocia. This was observed in two of four infants in the series. Hydrops foetalis is the fatal type of erythroblastosis. All four infants in this group perished. Intrapartum diagnosis of hydrops foetalis is possible by x-ray examination. It should be regularly employed when a history of recurrent stillbirths or definite erythroblastosis is obtained. Icterus gravis is a severe form of erythroblastosis; fifteen of twenty infants succumbed. Jaundice is the most prominent symptom but may not appear for from twenty-four to forty-eight hours after birth. There is enlargement of the liver and spleen. Cerebral hemorrhage is frequent and often precludes recovery. Anemia haemolytica neonatorum is the mildest form of erythroblastosis; all three infants recovered. Pallor of the skin and mucous membranes may be preceded by mild icterus. Enlargement of the liver and spleen, or both, and an increased number of normoblasts in the smear afford prompt diagnosis. Early and repeated transfusions comprise the ideal method of therapy for icterus gravis. The five infants who recovered received such prompt treatment. Iron and liver extract are valuable adjuncts to transfusion in the anemia group. A history of repeated stillbirths indicates careful search for erythroblastosis as the underlying cause.

Respiration Pyelography.—Bacon employed respiration pyelography in more than 200 cases during the past three years. Respiration pyelography, in his opinion, does not replace routine pyelography but is a valuable supplement. Respiration pyelography in the supine position is indicated when a knowledge of restricted renal or ureteral mobility will be of value. The author prefers it to postural study in these cases because of the ease and accuracy with which it can be carried out. Where the problem is one of excessive mobility and ureteral obstruction, the behavior of the upper urinary tract must be investigated in the supine and in the erect postures. The essential inspiration exposure may be supplemented by a diaphasic film, from which may be obtained information regarding relationship of the several parts in the two phases of respiration. The author recommends respiration pyelography as a simple supplementary roentgenographic procedure capable of producing accurately a permanent record of the phenomenon of renal motion. Single film respiration pyelography is a simple procedure which can be utilized wherever pyelography is done. Renal mobility can be estimated in 90 per cent of cases studied in this manner. A movable diaphragm is a sine qua non for normal renal mobility, since the perirenal fascia is a direct extension from the diaphragm. Renal and ureteral anomalies are more adequately demonstrated by means of respiration pyelography than by simple pyelography. The estimation of renal mobility in case of calculus, pyonephrosis and parenchymal and cortical renal lesions gives information which is obtainable in no other manner. Respiration pyelography is a valuable diagnostic procedure in perinephric abscess; renal fixation indicates perirenal involvement. The development and use of respiration pyelography have stimulated a sharper interest in the behavior of the diaphragm and adjacent structures in health and disease.

Preoperative Irradiation of Breast.—Howes and Bolker submitted a series of advanced lesions of the breast to intensive preoperative roentgen therapy. Proof of the malignant character of the lesion should first be obtained, either by means of a small surgical incision or needle biopsy if large doses are to be given, such as would produce violent skin reactions or pleural pneumonia. The entire breast is crossfired with parallel x-ray beams; one portal is directed through the breast from its medial margin, the other approaches the breast laterally and from behind. The path of the ray is directed so that the beam emerges through the opposite side of the breast and is not

directed down into the lung bed. An additional portal to the breast from below may be included. The size of the portal varies from 8 by 10 cm. to 10 by 15 cm. and includes the whole glandular element of the breast. Two hundred roentgens is delivered to each of these two portals for from five to six days a week. The total skin dose is limited not to exceed 6,000 roentgens. The other factors used are 40 to 50 cm. skin-target distance, 200 kilovolts, filtration 2 mm. of copper and 1 mm. of aluminum, half-value layer 1.90 mm. of copper, approximately 20 roentgens per minute. The supraclavicular area is next crossfired through an anterior and posterior portal, usually 8 by 10 cm. in diameter. The axillary portals measure 8 by 10 cm. or 10 by 12 cm. and may be used last, as the cutaneous reaction in both the breast and the supraclavicular areas is by this time distinctly visible and thus the danger of overlapping or allowing a ribbon-like band of unirradiated tissue to remain is minimized. Such a series requires from seven to twelve weeks to complete and the cutaneous reaction in the axilla and other parts is at its height ten days after the last dose. All of the reaction and reepithelization is completed from six weeks to two months following the treatments. After a two to three months interval, radical mastectomy follows. The tumor will often shrink to a small percentage of its original size and metastatic glands in the axilla have been similarly influenced. On the other hand, the authors have had several failures in reducing the size of the original growth and in two instances the mass increased in size during or immediately following radiation therapy. The reduction in size of the tumor often produces an excellent psychologic reaction. Three patients, however, refused operation following this initial response to irradiation. One has since died of liver metastases. Comparison with preirradiation biopsy permitted observation on the microscopic changes caused by irradiation. The final determination of the efficacy of this procedure is derived from a three to five year end-result. As the time interval in this series has been too short and the series of cases limited in number, no tabulation as to the end-results has as yet been prepared.

Relation of Histamine Headache to Migraine and Other Headaches.—According to von Storch, evidence has recently been presented which suggests that the mechanism of migraine headache is similar to that of the so-called histamine headache. It was his purpose in this study to investigate other aspects of the relation. A total of 125 experiments was performed on thirty-six patients subject to migraine headache, on twenty-three patients subject to chronic, recurrent nonmigraine headache and on fifteen persons free of headache. The experiments were of three different types. In type A a sudden intravenous injection was given of approximately 0.0034 mg. of histamine per pound (0.00755 mg. per kilogram) of body weight. This dose was regulated according to a tabulation of subthreshold doses; for example, 0.04 mg. was given to patients weighing between 115 and 145 pounds (52 and 66 Kg.). In type B 0.05 mg. of histamine phosphate was injected intravenously, irrespective of the subject's weight. Type C experiments consisted in first giving the proper subthreshold dose, according to tabulation. If this failed to produce headache, the procedure was repeated at three minute intervals, with an increase of 0.01 mg. each time until headache occurred. It was found that

headache may be produced by sudden intravenous injection of minute amounts of histamine phosphate in from 30 to 40 per cent of patients subject to chronic recurrent headache. The same procedure fails to cause headache in those who are free from this complaint. Apparently the threshold for histamine headache is lower among persons subject to chronic recurrent headache than among those not so afflicted. The threshold for histamine headache is somewhat lower for patients subject to migraine headache than for those subject to nonmigraine headache. Among patients subject to migraine attacks the type of headache produced by histamine is frequently similar to migraine headache. Among patients subject to other types of recurrent headache the type produced by histamine is only occasionally similar to the habitual headache. There was no evidence that the cranial vascular tree of patients subject to hemispheric migraine headache is unilaterally hypersensitive to histamine. These observations imply that in migraine and histamine headaches the mechanism productive of pain is somewhat similar.

Body Weight and Cancer.—Tannenbaum bases the possibility of a correlation between overweight and cancer mortality on laboratory observations of mice and on statistical data of a number of insurance companies. Experimentation with mice of various strains indicated a lower incidence of tumors and a greater longevity in mice which had been fed rations inferior in quantity by from one half to one third to those of full fed specimens. Analysis of the insurance statistics examined showed, with one exception, that overnutrition and overweight were significant factors in the histories of cancerous persons. Though the results of animal experimentation and of insurance observations strongly suggest a connection between body weight and cancer incidence, the author calls attention to the fact that body weight is the result of complex factors and that, in consequence, no necessarily direct and primary relationship may exist between cancer mortality and body weight. In fact, the factors controlling body weight may be directly more significant than body weight itself. Furthermore, cancer is not a single entity but a group of conditions. Correlation between body weight and carcinoma may therefore exist for some kinds of tumors and not for others. The establishment and maintenance of body weight levels at a minimum compatible with general good health, possibly from 10 to 20 pounds below accepted "normal" levels, may have prophylactic value or at least delay the appearance of the tumor. Further clarification of the relation between cancer and body weight, the author believes, may come from the laboratory where animal material can be controlled and the difficulties inherent in studies on man be eliminated.

Oral versus Parenteral Pollen Therapy.—Alperstein evaluated the therapeutic effect of the oral method of pollen therapy as compared with the parenteral. Fifty patients sensitive to ragweed were placed on the oral pollen therapy. They reported twice a week preseasonally and were given each time a capsule of dried ragweed pollen. The first dose consisted of 500 noon pollen units and doses were gradually increased until a total of 90,000 noon units per dose had been reached. The dose was then reduced to 60,000 noon units. The fifty patients taking oral therapy could be divided into two groups. The first group of twenty-six had not taken treatment for hay fever in previous seasons. These twenty-six reported that they had had (before 1938) from moderate to severe symptoms. During this season (the fall of 1938) on oral pollen therapy, twelve of twenty-six, or 46 per cent, obtained above average relief, whereas eight of twenty-six, or 31 per cent, received no relief. A second group consisting of twenty-four patients had been treated parenterally in prior seasons. These patients obtained better results in 1938 on oral therapy than before 1938 on the parenteral method. In this second group the results were better than in the first group. Here only four failed to get relief, while in the first group there were eight. A conclusion may be made that an added impetus toward improvement in the second group was due to the cumulative effect of parenteral treatment in previous seasons. The failures in both groups had multiple sensitivities (to foods and other inhalants). This may account for the few

poor results. Neither the site of allergic manifestations nor the degree of sensitivity bore any relation to clinical relief of symptoms under any mode of treatment. Unpredictable reactions occurred with the oral method. The range of dosage (by the oral method) within which reactions occurred was quite wide, anywhere from 1,000 to 90,000 noon units. The reactions were of three types, gastrointestinal, respiratory and systemic. The parenteral method gave a greater percentage of satisfactory relief as well as a smaller percentage of complete failures than did the oral method. In view of the unpredictable reactions, a rigid schedule for oral pollen therapy cannot be planned for self administration by patients. It is inadvisable to allow patients to treat themselves by the oral method. The experiments with the blood and urine of patients treated orally show that (a) an appreciable amount of pollen is absorbed through the gastrointestinal tract and (b) reagin and allergen coexist in the circulating blood at the same time at the height of treatment. The oral method is not recommended, as it has no particular advantage over the parenteral method; nor do the results obtained show nearly as much beneficial clinical relief as those obtained by the parenteral method.

Pneumoperitoneum in Pulmonary Tuberculosis.—

According to Boislaniere and his collaborators, numerous investigators have reported in the last three decades experiences with pneumoperitoneum in tuberculous enteritis and peritonitis with apparently satisfactory results. Banyai was first to observe the effect of pneumoperitoneum on pulmonary tuberculosis. The authors have employed this method during the last eighteen months in fifty cases of pulmonary tuberculosis at Mount St. Rose Sanatorium. The patient is placed on his back. At a point just to the left of the rectus muscle and midway between the umbilicus and the lower costal border in the left upper quadrant of the abdomen, or at a point 2 inches below and lateral to the umbilicus, the area is swabbed with tincture of iodine and alcohol. An infiltration is made with 0.5 per cent procaine hydrochloride solution through the skin down to the peritoneum, with use of from 3 to 5 cc. of the local anesthetic. An 18 or 19 gauge pneumothorax needle is introduced through the anesthetized area into the peritoneal cavity and is connected with the pneumothorax apparatus. The needle is introduced at a slight angle to avoid direct pressure on the viscera. The amount of air usually administered at the first treatment is about 300 cc. Thereafter, at weekly intervals, amounts varying from 500 to 1,500 cc. are given, depending on the extent of the elevation of the diaphragm desired. Occasionally after the initial treatment there is slight discomfort resulting from the displace-

ment of the abdominal viscera. Usually the pain in the shoulder region and sides of the chest disappears within twenty-four hours. The mechanical effects of this procedure are (1) bilateral elevation of the domes of the diaphragm, (2) separation of the liver, spleen and stomach from the diaphragm, (3) diminution in the size of the thoracic cage, favoring a selective collapse of the diseased lung tissue and (4) selective elevation of one of the domes of the diaphragm, especially in a unilateral involvement. The mechanical effects result in the following physiologic changes: (1) lymph stasis which favors fibrous tissue formation, (2) tissue anoxemia in which tubercle bacilli cannot grow, (3) pulmonary congestion which inhibits the growth of the tubercle bacillus and (4) approximately 15 to 35 per cent reduction in the chest capacity. Twenty-six of the fifty patients were hopeless but showed a marked improvement following pneumoperitoneum. The treatment is indicated in all cases in which other methods of treatment have failed or in which such measures are contraindicated by the nature and extent of the involvement. The authors list a number of indications but admit that time alone will determine its ultimate value. They stress that the psychic effect of pneumoperitoneum is valuable, especially in the advanced cases. They do not claim that it will cure these cases, but it will relieve toxemia and prolong life.

Antitoxin in Experimental Tetanus.—Shumacker and his associates present studies on the best mode of administering tetanus antitoxin. They describe six series of experiments which demonstrate that tetanus antitoxin administered intrathecally is superior to that given intravenously in guinea pigs having received more than a lethal dose of tetanus toxin and exhibiting local tetanus, and in dogs poisoned with more than a lethal dose of toxin and showing signs of both local and general tetanus. The authors admit that their experiments do not constitute the first attempt to evaluate the therapeutic effect of intrathecal injections of antitoxin. They offer an explanation for the failure of other workers in demonstrating the superiority of antitoxin administered by intrathecal injection. Their own experiments demonstrate that the superiority of intrathecal injection holds true with general as well as with local tetanus. They feel that tetanus antitoxin given in proper amount intrathecally will be found superior to antitoxin administered intravenously in any animal poisoned with a lethal quantity of tetanus toxin, with evident symptoms of tetanus, and yet before a fatal amount of toxin has been fixed. They believe that this will hold true for any animal, tetanus sensitive or tetanus resistant, including man, and that it will hold true whether the toxin is injected into the body or liberated from tetanus organisms in the body tissue. Certain problems remain to be solved such as whether repeated intrathecal injections are more beneficial than a single one and whether the lumbar subarachnoid route is as efficacious as the cisternal.

Congestive Splenomegaly Without Hepatic Cirrhosis.—According to Rousselot, the usual intrahepatic lesion producing congestive splenomegaly is cirrhosis of the liver. In this report, however, he is concerned with a selected group of fifteen patients all presenting the typical symptoms usually associated with Banti's syndrome and all with gastrointestinal bleeding as a dominant symptom, and yet in no case was there coexistent liver cirrhosis. The nonexistence of hepatic cirrhosis was established by most of the available methods. These procedures included various liver function tests carried out before operation, gross examination of the liver at operation, and liver biopsy on one or more occasion in the same patient. There was evidence not only that cirrhosis was absent at the time of operation but that it did not develop, as established by the subsequent clinical course and further laboratory studies for varying periods up to nineteen years after operation. The etiology of splenomegaly can be explained on a mechanical basis; an extrahepatic obstructive factor was demonstrable in the portal venous system of eight of the fifteen patients examined. This was recognized at the operating table in four instances, and four times it was demonstrable only at autopsy. The failure to discover an obstructive factor in the other seven cases is not necessarily a weakness in

the author's hypothesis but is due rather to the technical difficulties involved in an operative examination of the portal venous bed away from the splenic hilus, particularly behind the head of the pancreas. The nature of the extrahepatic lesions responsible for obstruction to splenic blood was thrombosis of the splenic vein, thrombosis at the junction of the splenic with the portal vein, stenosis of the portal vein just below the liver, stenosis of the portal vein above the entrance of the splenic vein, cavernomatous transformation of the portal vein and cavernomatous transformation of the junction of the portal vein and splenic veins. In every instance in which splenic vein pressures were taken at operation, a "portal hypertension" could be determined. The evidence presented contradicts the sequence described by Banti of a primary splenomegaly and a subsequent cirrhosis due to a hypothetical toxic agent. The author stresses the frequency of anomalies in the portal system. In this group of cases of congestive splenomegaly due to extrahepatic obstructive lesions the prognosis and variations in clinical behavior were dependent on two factors: (1) the site of the obstructive lesion and (2) variants in the anatomy of the venous pattern. As far as the author knows, this concept is presented for the first time.

Prophylactic Use of Sulfanilamide in Abdominal Surgery.—Lockwood and Ravdin began in 1938 to resort to sulfanilamide in the treatment of inflammatory and traumatic bowel perforations. Impressed with some of the recoveries, they have introduced prophylactic use of sulfanilamide in all bowel resections. A series of twenty-two consecutive colon resections of various types, sixteen for carcinoma and six for nonmalignant lesions, is presented. The type of operation varied with the location and extent of the lesion and the condition of the patient. Ileocolostomy, employing an open technic, was employed in six instances. In the rest the involved bowel was resected and one or both ends of the resected intestine were brought out as a terminal or a double-barrel colostomy. In no case was there clinical evidence of peritonitis during the postoperative course. One death was due to coronary occlusion on the first postoperative day. This series is small and of doubtful statistical significance. The authors, however, have been encouraged by the results of prophylactic sulfanilamide therapy in the first year of its trial. They present six instances of inflammatory and traumatic perforation of the intestinal tract in which sulfanilamide treatment was used. The recovery of the two patients with local peritonitis associated with sigmoid diverticulitis is perhaps not at all remarkable, but in the other four cases the nature of the lesions found at operation and the immediate condition of the individual patients was such as to lead the authors to believe that the prognosis was extremely grave. Surgeons have been hesitant to employ sulfanilamide and its derivatives in the prevention and treatment of peritonitis of intestinal origin because of a well entrenched belief that sulfanilamide is effective only in infections due to certain cocci. The authors gained the impression that, under special experimental or pathologic conditions which favor drug action, sulfanilamide may have some degree of antibacterial effect against almost all species of pathogenic bacteria. Peritonitis of intestinal origin is a polymicrobial infection, and the bacteria concerned in its production are relatively, but not entirely, resistant to sulfanilamide bacteriostasis. This bacteriostatic effect may become significant in the peritoneal defense against postoperative peritonitis if an adequate concentration of the drug is present, if the number of contaminating organisms is small, if tissue necrosis is minimal and if the usual cellular defense is present. Clinical experience is as yet insufficient to warrant a final conclusion as to the effectiveness of sulfanilamide in the prevention of peritonitis.

Use of Fresh and Stored Blood in Hemorrhages.

Brewer and his associates sought to determine the relative therapeutic value of fresh blood (stored for less than twenty-four hours) and stored blood (kept from ten to fourteen days) in acute and nonacute hemorrhage and the relative incidence and character of the reactions on the basis of 153 cases (fifty-eight fresh blood, ninety-five stored blood). The transfused blood used was mixed in the ratio of two parts of blood to one part of a solution consisting of 3 per cent dextrose in 0.85 per cent sodium chloride and 1.05 per cent sodium citrate. The investigators were in full accord that stored blood was as valuable as fresh blood in the treatment of acute hemorrhages but were not so certain in nonhemorrhagic involvements. Stored blood in many cases gave a rise in hemoglobin (Haldane's method) as high as that produced by fresh blood. However, on the average, the gain was greater with fresh blood. For purposes of comparison, hemoglobin readings were taken at approximately twenty-four hours, forty-eight hours and after the fifth to the seventh day after transfusion. Differences in blood pressure for the two blood groups showed a remarkable equality; those in pulse rate were very small and could be attributed to chance. Mild reactions, excluding rise of temperature, occurred more commonly after the use of stored blood. Severe rigor was found to be practically identical in the wake of either blood transfusion (4.7 as against 5.4 per cent). In no case was a really serious reaction with jaundice and hemoglobinuria noted or a difference in the rise of temperature after the use of fresh or stored blood in nonacute hemorrhages whether used warm or cold. However, it was found to be advantageous to warm blood to approximately body temperature. The analysis revealed no connection between the amount of blood given and the risk of reactions or between the rate of administration and the risk of reactions. In a total of 153 cases no severe hemolytic reaction occurred nor fatal results attributable to the transfusion. The authors indicate that the subject requires further study.

*Prognosis in Diabetes in Childhood: Review of Seventy Cases. D. H. Wallace.—p. 1.

Thrombosis of Abdominal Aorta, with Report of Case. J. Ronald and Margaret Leslie.—p. 7.

Prognosis in Diabetes of Childhood.—Wallace points out that since the discovery of insulin the outlook in diabetes has undergone a complete change, especially with regard to children. Whereas in preinsulin days few children lived for more than two years after the onset of the disease, now prospects of life and of a reasonably comfortable and useful existence are greatly enhanced. An analysis is presented of the results of treatment of patients admitted to the Royal Hospital for Sick Children, Yorkhill, since the institution of insulin therapy in 1924. Seventy-seven cases have come under observation. Of this number seventy have been followed up with a view of determining the initial and late results of control and supervision. Eighteen of the seventy have died: four in coma associated with some infection, two of uncomplicated infection, eleven in coma

without any other cause and one from prematurity and atresia of the pancreas. The average duration of life in these eighteen cases was 2.3 years. The majority of the deaths occurred within two years of the onset of the disease. The prognosis improves in children who have survived for longer than that period. The mortality rate was higher in those patients who did not attend the outpatient clinic after dismissal from the hospital than in those who did attend. The average duration of the disease in the fifty-two patients who are still alive has been 4.14 years. In these, tolerance has improved in seventeen cases, has diminished in twenty-six and is stationary in nine.

Convulsion Therapy with Ammonium Chloride.—Dax used pure ammonium chloride, 10 cc. of a 5 per cent solution given as rapidly as possible, to produce convulsions in twenty-four mentally disordered patients. The injections were given twice a week. Sixteen of the patients had received no previous treatment, four had completed a course with metrazol or azoman (3-ethyl-4-cyclohexyl-1, 2, 4-triazol) without success and four received injections during a course which had been commenced with metrazol or azoman. Ten of the sixteen patients had schizophrenia from two to ten years. Of the other six patients, one had involutional melancholia, two had mania with no signs of recovery, one was confused and not improving and the other two were depressed. Of the schizophrenic patients the one acutely affected had thirteen injections of ammonium chloride with some improvement, though she remained impulsive in her actions, hallucinated for hearing and uncertain in conduct. After nine injections of metrazol she recovered and has been discharged. A girl with a previous remission recovered and was discharged after nine ammonium chloride convulsions. Of the remaining eight patients four showed improvement, one had heart failure after five convulsions though making good progress and three were no better and were given other convulsants. The patient with involutional melancholia had twenty fits with improvement and now appears to be recovering. The confused patient had ten injections with little change and is now awaiting discharge after three metrazol convulsions. One of the patients with melancholia had twenty ammonium chloride fits with only moderate improvement. One injection of metrazol was given, but she complained of pain following the fit and a small fracture of a dorsal vertebra was found. The other melancholic patient had thirteen fits with ammonium chloride, resulting in only a slight improvement, but after four injections of metrazol she recovered. One patient with mania showed little improvement with ammonium chloride and has improved on other convulsants. The other mania patient had ten ammonium chloride convulsions and became a little less restless; these were followed by one injection of metrazol, one of azoman and three of ammonium chloride; she then recovered. The four patients who had previously been given convulsion therapy were schizophrenic. Two had fifteen ammonium chloride convulsions without effect. The other two, given sixteen and twenty-eight injections of ammonium chloride respectively, have

shown considerable improvement. Both have been ill for more than three years and previous treatment with metrazol and azoman gave little improvement. Of the four remaining patients only one improved considerably after eleven metrazol injections and was discharged as recovered after a further ten convulsions with ammonium chloride had been given. The author states that the muscular movements following ammonium chloride injections are so slight, in comparison with the convulsions produced by other drugs, that the risks of fracture or dislocation appear negligible provided the staff does not interfere during the fit. The results of ammonium chloride convulsions are not nearly as good as when metrazol or azoman is used; however, the risk of fractures is negligible and the elevation of blood pressure after the fit is comparatively small. It may be found useful in completing courses of treatment after an improvement has been obtained with other drugs. It seems worth trying when metrazol or azoman has failed and it may prove useful for the older, more feeble or bedridden patients.

Closed Plaster Treatment of Infected Wounds.—Girdlestone thinks that there is no need to reject enclosure of the wound and immobilization of the soft tissues, because the full ritual is in part contraindicated. 1. In the débridement, the general rule is to excise, as far as practicable, infected tissues and tissues devitalized by bruising or by the impairment of circulation. 2. It is advisable to lay open rather than suture when suturing would involve tension and devitalization of the skin or deep parts. 3. There should be a varying degree of "saucerization," which allows natural retraction of the muscles to the position of equilibrium and involves a laying open for free drainage of all pockets or areas of heavily infected or damaged tissue which cannot properly be excised. For serious destructive wounds the requirements vary from the saucer to the cup; but there are many wounds in which no such formidable exposure of the deep tissues is indicated. Nothing more may be needed than a layer of broad wick laid between the edges of the wound after débridement. 4. The plaster splintage has a dual purpose: (a) the restoration of function by keeping the bones, joints and muscles at rest in the chosen position; (b) defense against the spread of infection by keeping the cellular infiltration undisturbed in the tissues and lymph channels round the wound. 5. This is favored by a particular technic of enclosure of the wound in that part of the plaster which covers the exposed tissues. It should apply an even gentle pressure similar to that normally exercised by the fascia and the skin. 6. The closed plaster treatment eliminates frequent dressings, which mean either pain or repeated anesthesia for the patient and are both time consuming and expensive. It has been said that after two or three days the closed plaster method is not applicable to a dirty wound because excision is no longer practicable. This is a great mistake, for in the author's opinion no method of treating can compare with closed plaster after saucerization, which may include laying open all heavily infected areas. A wound that will benefit from saucerization and enclosure does not always need excision; indeed, excision is generally contraindicated in the presence of established sepsis. On the other hand a late wound which has been unsuccessfully treated by excision and suture may need the whole ritual. It has been said that for wounds near a joint this method is unsatisfactory on account of resultant stiffness. It is true that when early excision and suture without tension can be undertaken the method need not be applied. But where the wound has involved widespread laceration and devitalization of tissues or where, owing to lapse of time, there is spreading infection, the closed plaster method gives not only relative safety of life and limb but also a better prospect of movement. The method has been

decried because a number of wounded men have reached the hospital with wounds doing badly from extensive pressure sores. Probably the surgeons were imperfectly familiar with the method, for he who would apply plaster in war must be skilful in its use or he will be a danger to his patients and bring undue discredit on the method.

Vincent's Disease Treated with Nicotinic Acid.—King directs attention to the possibility of an association between pellagra and Vincent's disease. He was told by Platt that among the natives of Nyasaland an inflammation of the gums was common and that smears showed the organisms typical of Vincent's angina. Since these lesions did not respond to vitamin C or to local treatment with neoarsphenamine it was thought that the gingivitis might be an early manifestation of pellagra, which is common in Nyasaland and therefore might be cured with nicotinic acid. In a case in which cooperation could be obtained, a week's course of nicotinic acid effected cure. Reports on pellagra reveal that stomatitis and glossitis are nearly always present. Indeed the effect of various treatments on these oral manifestations of pellagra has been used as a criterion of their efficacy. Moreover, in typical cases of pellagra fusiform bacilli and *Spirochaeta vincenti* are commonly found. Four cases of severe Vincent's disease were successfully treated with nicotinic acid by mouth. Inoculation of the author's mouth with infected material from a severely affected patient failed to induce inflammation or ulceration. The organisms grew in abundance for a short time, but they had disappeared three days after the inoculation. A similar experiment on a monkey caused gingivitis, which subsided within ten days without treatment. A study was begun of the excretion of nicotinic acid in the urine of four persons with "normal" gums and of one with Vincent's gingivitis. The patient with Vincent's angina showed an abnormally small amount of nicotinic acid excreted in the urine compared to that of the four people with healthy mouths. A larger number of investigations is necessary before conclusions can be drawn. It is suggested that Vincent's disease may be related to deficient intake or utilization of nicotinic acid and its allied pyridine derivatives of the vitamin B₂ complex. The author's failure to sustain the growth of fusiform bacilli and spirochetes in his mouth and their relatively rapid disappearance from a monkey's mouth suggest that spread of the disease may be determined by some constitutional factor. The experiences of health authorities during the last war, however, makes it still advisable to treat the lesions as infectious.

The Schultz Syndrome (Granulocytopenia).—Drevermann and Gardner report six cases of Schultz syndrome, granulocytopenia, and four cases of other blood dyscrasias (myeloid, lymphatic and monocytic leukemia and aplastic

anemia). Some patients recover without any treatment other than cessation of the causal drug, but the condition must be treated as a medical emergency because death may follow the onset and therefore the withholding of any form of recommended treatment is not justified. Treatment includes roentgen therapy, nucleic acid, pentnucleotide and liver extract. Roentgen therapy is regarded as useless. More recently, extract of yellow bone marrow has been used. The authors have followed the method of Zichis for the preparation of the extract but have carried the saponification further and have obtained a product similar in appearance to that of Marberg and Wiles. Arrest in development of the polymorphonuclear cells may take place at different stages and a special substance may be required for each, and since it is not possible to distinguish clinically the stage at which arrest has occurred the authors suggest that pentnucleotide and yellow bone marrow extract be given simultaneously to all patients. Each may play a part in the maturation of the polymorphonuclear leukocytes. In some cases liver extract may prove to be of value. Two recoveries have been had with marrow extract. In another case the blood picture returned to normal; but, despite this, death occurred. The other three patients failed to respond when treated with marrow extract and/or pentnucleotide. Therefore marrow extract is not specific in all cases and should be used in conjunction with pentnucleotide. Marrow extract was of no value in the other four blood dyscrasias. All four patients died.

Oral Treatment of Gonorrhea with Sulfapyridine.—Meier reports on oral treatment of 173 cases of gonorrhea with sulfapyridine. Most patients received one course of treatment of thirty tablets in decreasing doses within six days. Where the first course of treatment did not bring about a complete cure, a second course of thirty-six tablets was given from ten to fourteen days later. Local treatment was also administered. Ninety-five and nine tenths per cent of the patients were cured, with men reacting slightly better to the drug. Sulfapyridine was effective in new as well as in chronic cases and satisfactory results were obtained in complicated cases. There were slight reactions in forty-five cases and cutaneous rashes of brief duration in two instances. A survey of the literature reveals that on the average 86.7 per cent of 1,586 cases of gonorrhea were cured with sulfapyridine. Higher dosage with local treatment was observed to produce better results than lower dosage without local treatment.

- *Cancer of Testes: Present Status of Knowledge. R. Bernardi.—p. 57.
Anorectal Fistulas: Classification. J. A. Garat.—p. 97.

Cancer of Testes.—Bernardi discusses the diagnosis, prognosis and treatment of cancer of the testes and presents a review of the literature and results of his experience in thirty-two cases. The incidence of testicular cancer is from 0.5 to 2 per cent as compared with cancer of other structures. The incidence of cancer in ectopic testes not operated on is from 0.5 to 2 per cent as frequent as that of cancer of the normal testes. Cancer of an ectopic testis which has been brought down into the scrotum by surgical intervention is more common than it is in the ectopic nontreated testis. Testicular cancer develops without giving rise to early symptoms, with more or less acute increase in the volume of the organ and a change in its consistency. Chevassu's palpation of the epididymis and certain hormonal tests are the most reliable diagnostic procedures. Hormonal reactions give positive results between the first and third month of the appearance of local symptoms and in recurrence or the appearance of metastases.

The more malignant the type of tumor, the higher the figures of the reaction, the highest figure being obtained in chorion-epithelioma. Negative results of hormonal reactions suggest the absence of a testicular tumor or the presence of a teratoma. Prognosis depends on the nature and histologic structure of the tumor, the absence or presence of metastases, their seat and extent and especially on the early diagnosis and the opportunity of an early castration preceded and followed by roentgen irradiation. The author advises castration even in the presence of a tumor sensitive to irradiation and systematic roentgen therapy before and after castration with preoperative irradiation of the supraclavicular and lumbothoracic lymphatic chain and postoperative irradiation of the mediastinal and left supraclavicular regions. The course of the disease after castration and roentgen therapy is periodically controlled by repeated hormonal tests, positive results indicating the advisability of further roentgen therapy. This treatment was practiced in ten of the thirty-two cases. Satisfactory results were obtained in the absence of metastases. In cases of lumbo-aortic metastases irradiation diminished their size and alleviated the pain.

Several Unusual Lesions of External Male Genitalia. J. H. Maasland.—p. 1659.

Determination of Nicotinic Acid in Nutritional Edema.—According to van Veen and Dhanodibrotu, nutritional edema occurred rather frequently in central Java during 1939. Successive crop failures were the cause. It is noteworthy that, although the nutrition was deficient in many respects, only edema and sometimes slight pellagra-like symptoms but no other deficiency symptoms were observed. Diet surveys and medical examinations were made. A number of analyses were done on the vitamin A, vitamin B₁, nicotinic acid and protein contents of the blood of patients with nutritional edema and of the members of their families. The blood of patients with nutritional edema, some of whom showed pellagra-like symptoms, was analyzed for the concentration of nicotinic acid when the patients entered the hospital. Because the nutrition had been deficient for a long time and in practically every respect, it was to be foreseen that no pure and uniform deficiency syndromes would appear. Moreover, these syndromes were blurred by ancylostomiasis, which is a frequent concomitant of poor nutrition, and sometimes by various other diseases (malaria, dysenteries). In some cases a low content of nicotinic acid was found in the urine but since it was impossible to get the twenty-four hour volumes or to learn whether anuresis or diuresis was present when the patients entered the hospital these determinations do not have great value. More attention was paid to the determination of the nicotinic acid level in the blood. Low nicotinic acid levels frequently occurred in the blood of the patients with edema. These low values were, however, not to be directly connected with the slight pellagra-like symptoms or with the so-called porphyrin reaction of Beck-Elfinger-Spies. On the other hand the authors found a rather close connection with the blood cell volume (as determined by the hematocrit) in the sense that a low nicotinic acid level was almost always attended by a low cell volume, which was of frequent occurrence in these chronically underfed, mostly anemic patients with edema. This connection between nicotinic acid content and hematocrit value depends on the fact that a nicotinic acid does not occur in the blood serum. With a normal cell volume a normal nicotinic acid level was usually found, but at the same time pellagra-like dermal symptoms would sometimes occur. It is likely not only that the food (chiefly Indian corn) of the patients with nutritional edema is deficient in nicotinic acid but also that the conveying capacity of the blood for nicotinic acid has been reduced by the low cell volume. It would be interesting to know whether low cell values play a part also in the nicotinic acid supply of patients with classic pellagra.

FASCIAL REPAIR OF INGUINAL HERNIAS

REPORT OF 760 OPERATIONS FROM JANUARY 1934
TO JANUARY 1939

CHAIRMAN'S ADDRESS

THOMAS M. JOYCE, M.D.

PORTLAND, ORE.

Today the surgeon in almost every instance can assure the patient with inguinal hernia that he will be cured. Yet less than six decades ago such assurance was the exception rather than the rule. Up to that time treatment of this ancient affliction had been principally palliative.¹ In the earliest times bandages were applied to retain reducible hernias. Later the truss was introduced and throughout the centuries of its use underwent numerous modifications. Poultices and plasters of various astringent and tonic substances were long popular. Frequently a red hot cautery, varying in size and shape with the individual patient, was applied to the skin over the area of protrusion, which had previously been outlined with ink. Caustic agents were similarly employed. The object of both the cautery and the caustics appears to have been to destroy the tissues and thus to produce granulation firm enough to prevent recurrence of the protrusion. As late as the nineteenth century the first procedure resorted to in the treatment of strangulated hernia was the ancient one of taxis. When this failed, bleeding, warm baths, purgatives, opiates, local cold applications and finally tobacco clysters were tried. The ensuing faintness of the patient was believed to cause relaxation of the involved areas and so to facilitate reduction of the extruding viscera. Lawrence¹ also mentioned the local application of cupping glasses and leeches for relief of strangulation.

The injection treatment of hernia is probably almost 150 years old. According to Fowler² the Frenchman Desault, who died in 1795, treated the combined hernia and hydrocele of a 9 year old boy with injections of red wine into the scrotum and lower part of the canal. Some fifty years later this form of treatment was again practiced by workers in Europe and America.³ Both

the fluids used and the manner of injecting them varied. This means of managing hernias, however, made slow progress and with the advent of improved surgical procedures was almost forgotten. Within recent times it has once more been revived and today is widely used.

While operation for nonstrangulated hernia was practiced as early as the first century and quite possibly before that, this mode of treatment was not developed until hundreds of years later.⁴ In the middle ages the operative field was almost entirely dominated by unskilled traveling "rupture curers," many of whom were unscrupulous quacks who not only failed to effect a cure but sacrificed the testicles of their unsuspecting victims as well. On the other hand, there were gifted men among them who not only improved the prevailing treatments but devised valuable new ones. It was a celebrated rupture and stone cutter of the sixteenth century, Pierre Franco, who undertook operation for relief of incarcerated hernia, a procedure avoided up to that time. With the reintroduction of dissection of human bodies in the sixteenth century, careful study of the structures involved in the formation of hernias was made possible. Significant and revolutionary contributions began to appear and new interest in the surgical treatment of hernias was gradually stimulated. By the beginning of the nineteenth century the anatomy of hernias was well understood. Operations for strangulated hernias were relatively frequent. Then, as now, the technics followed varied considerably. The results obtained, however, were far from favorable, so that surgical intervention was resorted to only after all other procedures had failed. It was not until anesthesia was accepted and Lister's principles of antiseptics were established that the greatest obstacles to the ultimate successful treatment of hernia were removed.

In 1892 Marcy,⁵ Lister's first American pupil, argued that delayed operative intervention and not the operation was responsible for the unsatisfactory results of that period. He called attention to the fact that Sir Astley Cooper,⁶ "even in his day" (the beginning of the nineteenth century), "when the lack of anesthetics and of the requisite knowledge of proper wound treatment rendered the operation truly formidable," had recognized "the fatal error of delay." Marcy is credited with being the first to have practiced exposure of the inguinal canal by dissection, high ligation of the sac and plastic repair of the inguinal canal. In 1881 he⁷ had advocated the use of absorbable kangaroo tendon sutures.

Within a few months of each other, in 1889, appeared the independent reports of the operations devised by

From St. Vincent's Hospital and the University of Oregon Medical School Hospitals.

Read before the Section on Surgery, General and Abdominal, at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

Bassini of Italy and Halsted of America. In essentials, the two operations were the same. Bassini⁸ did a high ligation and dissection of the sac, brought the cord out through the muscles at the internal ring, placed the transplanted cord so that it lay on the internal oblique muscle and sutured the internal oblique muscle to Poupart's ligament—attempting in his repair to reestablish the obliquity of the canal. Halsted¹ constructed a new canal and a new external ring. Like Bassini, he ligated the sac as high as possible and sutured the internal oblique muscle to Poupart's ligament. The cord, however, he transplanted superficial to the aponeurosis of the external oblique. It was not long before Halsted began to modify his original technic. First he deemed it unnecessary to transplant the cord, then he discontinued his earlier practice of excising some of the veins of the cord to make it smaller. Later he incorporated a flap from the anterior sheath of the rectus muscle. Finally he employed the cremaster muscle and its fascia to reinforce the lower bed of the canal and also overlapped the aponeurosis of the external oblique. Halsted considered high ligation of the sac the most important factor in the operation.

The principles of the methods devised by Bassini and by Halsted, as every surgeon knows, are still the basis of the repairs done today. The numerous modifications of these original operations are more or less variations in the manner of disposing of the cord and of reconstructing the inguinal canal in an attempt to attain a

Fig. 1.—Incision.

more solid repair and thus to prevent recurrence of the hernia.

Contributing in a large measure toward the reduction of the percentage of hernial recurrences is the utilization of fascia for reinforcing the repair, particularly in the form of sutures. McArthur was the first to employ liv-

ing tendon as suture material. In 1901 he⁹ published a preliminary description of his method of cutting a narrow strip from the aponeurosis of either flap of the split external oblique and suturing the structures to be apposed with these strips. Both fascial strips were left

Fig. 2.—Splitting fascia of external oblique exposure of cord, nerve and cremaster muscle.

attached at the pubic spine. Nine years later Kirschner¹⁰ reported a method of overlapping the deep Bassini sutures with a rectangular patch of fascia lata. One border of this "free" fascial transplant was quilted to Poupart's ligament, the others were quilted to the abdominal musculature. The cord was brought out through a slit in the upper medial border of the transplant. Gallie and LeMesurier¹¹ in 1921 presented the results of experiments which had led them to the conclusion that a strong repair of the abdominal wall could be obtained by means of narrow fascia lata sutures. They threaded the narrow strips of fascia lata into curved large eyed needles and united the structures by interweaving the fascial sutures across the opening. For the closure of large hernial openings Gallie¹² later recommended a many tailed fascial sheet. He pulled the "tails" through the abdominal wall and then tied each opposite pair over the opening. In 1934 Wangenstein¹³ described his method of repairing inguinal hernias by means of a pedicle graft from the iliotibial tract. The flap is swung into the wound up over Poupart's ligament and sutured over the cord.

The consensus at present appears to be that fascia is indicated only for hernias difficult to repair, among which are included direct inguinal, ventral and recurrent hernias. It has been my contention for some time that if fascia is desirable in the repair of difficult hernias it is just as desirable in the repair of hernias that are not difficult; furthermore, that a large percentage of recurrences could be prevented if fascia were used as a routine in the initial repair. In my own practice I repair all primary indirect inguinal and femoral hernias, as well as all direct inguinal, ventral and recurrent hernias, with fascial sutures. My technic is a modification of older procedures—combining Halsted's¹ early transplantation of the cord, Andrews' ¹⁴ imbrication of the aponeurosis of the external oblique and McArthur's ⁹ sutures from the external oblique fascia or Gallie and

external oblique has been exposed, all the areolar tissue is carefully removed from it with gauze. The fascia is then split in the line of its fibers, directly superior to the upper border of the inguinal canal, from a point above the external ring to well above the internal ring.

Fig. 3.—Separation of cremaster muscle from cord.

LeMesurier's ¹¹ fascia lata sutures. The most important factor in this technic is the suture of fascia only to fascia, a running fascial stitch being used for the deep line of sutures. It has been my experience that muscle sutured to fascia does not give a firm union because the muscle fibers have a tendency to separate. Gallie and LeMesurier ¹⁵ have had a similar experience. They stated that "side-to-side suture of muscle and aponeurosis, as in the suture of the internal oblique muscle to Poupart's ligament, results in union of practically no strength."

OPERATIVE PROCEDURE

An oblique incision, parallel to Poupart's ligament, is made through the skin and fat, high enough on the abdomen so that a bandage can later be applied without any inconvenience to the patient. After the fascia of the

HERNIA REPAIR—JOYCE

JOUR. A. M.
SEPT. 21, 1933

The interior flap is dissected free down to the shelving edge of Poupart's ligament and retracted; the superior flap is freed for about 2 cm. and also retracted. Care is taken to preserve the ilio-inguinal and iliohypogastric nerves and their branches.

Fig. 6.—Transfixion of stump of sac high under external oblique muscle.

When the canal has been exposed completely, the cremaster muscle is separated from the cord and dropped posteriorly. Next all the fat is carefully removed from the cord. After this the sac is picked up, freed from its attachments, opened and inspected, clamped, ligated as high as possible, and its stump transfixed well up under the external oblique muscle. When this is completed the cord is elevated and held aside with small tapes.

A strip of fascia, about one-fourth inch wide, is now cut from the edge of the fascia of the superior flap of the external oblique. The cutting is begun close to the muscle belly and continued down to the pubic spine, where the strip is left attached. As a rule, the fascial strip is about 5 inches long. This fascial strip is then threaded with a needle of smaller caliber than the so-called Gallie needle and secured in it with silk. The smaller needle does not separate the fibers as much as the larger Gallie needle, so that there is less possibility of subsequent weakness of the tissues through which the needle is drawn. With the fascial strip, which is used as a running stitch, the fascial border of the superior flap of the external oblique is sutured to the shelving edge of Poupart's ligament up to the internal ring. Here the fascial strip is locked both below and above the cord, leaving an opening just large enough for the cord to emerge without constriction. The approximation is then continued for the remaining length of the opening. After the suturing has been completed, the fascial end is firmly anchored with silk or with chromic catgut. The cord is now released from the tapes which had held

it aside. The inferior flap of the external oblique is brought over the cord and sutured with catgut to the fascia of the superior flap of the external oblique. The cutaneous tissue is closed with plain catgut, and the skin is closed with silk.

method on 149 private patients at St. Vincent's Hospital. Of these, 124 operations were traced. In this group there was one recurrence, a percentage of 0.8 (table 1).

Three hundred and ninety-one hernias on 337 patients were repaired with fascia in the University of Oregon Medical School Hospitals in a similar period. Twelve externs and residents performed 307 of these operations. The remaining eighty-four were performed by twelve staff surgeons. Of the 231 operations traced, 180 had been done by the externs and residents. There were fourteen recurrences, twelve of which followed the repairs by the inexperienced surgeons, a percentage of 6.3 for the inexperienced surgeons and 3.92 for the more experienced surgeons (table 1). An investigation was recently made of the higher recurrence rate in the

University of Oregon Medical School Hospitals. It was found that some surgeons had not followed explicitly all the details which had originally been emphasized in the fascia to fascia with fascia technic. In some instances muscle had been sutured to fascia with fascia, in others the external oblique had been brought over to the shelving edge of Poupart's ligament and sutured with chromic catgut. In these instances the muscle had pulled away from the line of suture. On the other hand, one resident who had followed every detail of the technic with meticulous care had no recurrences in forty-three traced operations. He had done seventy-five hernial repairs, a little more than one fourth of the total number performed by all the externs and residents.

Dr. Alanson Weeks,¹⁷ chief of staff of St. Luke's Hospital in San Francisco, using the same technic, has done 176 operations. He reported one recurrence, 0.56 per cent (table 1). In a recent communication, Dr. Weeks stated that he had given instructions to the other surgeons on the staff of St. Luke's Hospital to repair the inguinal hernias of all patients entering through the clinic of that hospital by the technic described in this paper.

Dr. Otto H. Pflueger¹⁷ of San Francisco did thirteen operations on twelve patients with this method. He has had no recurrences (table 1).

The average age of the patients was 48 years. Three patients were 14 years old, the youngest, and one patient was 84, the oldest. With the exception of one

Fig. 9.—Suturing of lower border of external oblique fascia to the shelving edge of Poupart's ligament.

man with bilateral recurrences, who was 46 and another who was 48, the age of each patient who had had a recurrence was 50 or over (table 2). By far the greatest number of operations was performed on male patients.

17. Personal communication to the author.

The majority of the recurrences, as nearly as could be determined, were discovered from three to ten months after operation. In three instances the hernias recurred a year, a year and a half and three years and nine months after the repair. In one instance the hernia

causes not related to the operation at intervals of from two to three years later.

The type of anesthesia used was of no consequence whatever.

SUMMARY

1. A large percentage of hernial recurrences could be prevented if fascia was used in the primary repair.
2. The most important factor in the method of repair of the canal here described is the suture of fascia only to fascia with fascia. The operation is simple to perform; there is little danger of excessive trauma and, when all the details as outlined are observed, the results are excellent.
3. The principal steps of the technic are (a) careful removal of all areolar tissue from the fascia of the external oblique; (b) separation of the cremaster muscle from the cord, care being taken to preserve the ilio-inguinal and iliohypogastric nerves and their branches; (c) removal of all fat from the cord; (d) high ligation and transfixion of the sac; (e) suture of the fascial edge of the superior flap of the split external oblique to the shelving border of Poupart's ligament with a narrow fascial strip from either the external oblique or the thigh; (f) bringing the inferior flap of the split external oblique over the cord, and (g) suturing the edge of the imbricated inferior flap to the fascia of the superior flap of the external oblique.
4. A total of 760 operations were performed on 674 patients. Of this number, 544 operations were traced.

Fig. 10.—Fascial suture almost completed; note fixation about internal ring.

was noted almost immediately after operation (table 2). This was the recurrence reported by Dr. Weeks. The patient had had an obstruction in the sigmoid which required abdominal operation, and the hernia wound had become infected. There were seven other wound infections, all following operations performed at the

TABLE 3.—Incidence of Postoperative Deaths

University of Oregon Medical School Hospitals. In this group there was one recurrence five months after operation. In my own practice I have had two infected wounds, each of which followed the fascial repair of a postoperative ventral hernia. There was no sloughing of the fascia, however, in either instance, and neither hernia recurred.

In a few instances swelling of the testicle was noted after operation. In every instance this subsided before the patient left the hospital. No atrophy of the testicle was observed.

There were five postoperative deaths (table 3) in the entire group of 674 patients, or 0.74 per cent. In three instances the principal cause of death was bronchopneumonia. One death was due to coronary thrombosis. The last was attributed to bilateral pulmonary embolism. This patient had had recurrent bilateral indirect hernias repaired. Twelve patients, or 1.79 per cent, died from

Fig. 11.—Completion of reconstructed inguinal canal.

There were sixteen recurrences, a percentage of 2.94 for all the traced operations. By individual surgeons or groups the incidence of recurrence was: Dr. Pfeuger, no recurrences in thirteen operations; Dr. Weeks, 0.56 per cent in 176; my associates and I, 0.80 per cent in 124; twelve staff surgeons of the University of Oregon Medical School Hospitals, 3.92 per cent in fifty-one,

and twelve externs and residents of the same hospitals, 6.66 per cent in 180 operations.

5. There were five postoperative deaths, or 0.74 per cent.

6. The average age was 48 years, the youngest patient being 14 and the oldest 84. In the majority of instances the age of the patients with recurrences was above 50.

7. There were eight wound infections. In two instances the infection was followed by recurrence of the hernia—almost immediately and five months after operation, respectively.

8. In all instances of swelling of the testicle the swelling subsided before the patient left the hospital. No testicular atrophy was observed.

THE MANAGEMENT OF ACUTE CRANIOCEREBRAL INJURIES

BERNARD S. BRODY, M.D.

NEW HAVEN, CONN.

In no field of medicine do there exist more sharply opposed views than those expressed by various investigators on the subject of trauma to the brain and its membranes. The variation in teaching by men of equally large experience is hopelessly confusing to the large number of practitioners who are faced with the problems of head injury. The dissemination of opinion concerning the treatment of cranial injuries is important because the automobile has increased enormously the number of such patients for physicians in out of the way places where the services of a neurosurgeon are not readily available.

The development of the modern treatment of trauma to the brain has been influenced particularly by the work of Kocher¹ and Cushing,² by Weed and his collaborators³ and as a result of the extensive experience which came out of the World War. Kocher and Cushing described the four classic stages of brain compression and Weed found that increased intracranial tension may be influenced by changing the osmotic pressure of the blood through the agency of hypertonic solutions. As an introduction to the classification of cranial injuries I have adopted the outline of Munro (table 1), which was included in a report of 1,494 cases treated at the Boston City Hospital over a period of four and a half years. Table 2 will give some idea concerning the mortality in Munro's⁴ series. A noteworthy point is the rather small percentage of subdural and extradural hematomas, of which there were only eighty in all. The first two groups, which together comprise a total of 1,211 patients, could be classified as nonoperative. The last two groups, totaling 159 patients, may or may not have required surgical treatment, depending on the character, extent and location of the fracture.

The great majority of patients then will recover with ordinary bed rest supplemented in some instances

by lumbar puncture or hypertonic solutions. Those patients with an uncomplicated concussion should be kept in bed for approximately ten to fourteen days. Roentgenograms of the skull, when needed for medico-legal reasons or otherwise, can be taken when the patient's condition warrants the effort. A diagnostic spinal puncture should be done at some time within the first week. Any small amount of bleeding which might have been present may be missed after seven days. For patients whose spinal fluid is bloody or whose period of unconsciousness is prolonged, the diagnosis of simple concussion alone is no longer tenable and the period of bed rest must be proportionately longer.

In the final analysis, responsibility to the patient with a cranial injury resolves itself into three categories: There is first the prevention of infection, second the treatment of increased intracranial pressure and lastly the management of depressed fractures.

PREVENTION OF INFECTION

The prevention of infection, for the most part, is simply a matter of giving prompt and efficient attention to lacerations of the scalp. Also included is the prompt administration of antisera in cases in which there are contaminated wounds. More rarely one is confronted with a patient who has definite evidence of a fracture through the mastoid or paranasal sinuses in the form of cerebrospinal otorrhea or rhinorrhea. The second condition is more frequently followed by meningitis than the former. In my opinion these patients should be started promptly on sulfapyridine as a preventive measure. This drug is used because the pneumococcus is the most common invading organism. If the patient develops meningitis, a change in therapy may be indicated depending on the outcome of the bacteriologic study. Cases are seen with persistent bleeding from the nose or ear in which it is difficult to determine whether an admixture of spinal fluid is present or not. X-ray examination may be able to settle this point, as for example a fracture through the cribriform plate would strongly suggest the presence of rhinorrhea. The laminagraph has been of considerable help in this regard. Patients with rhinorrhea should be placed on isolation precautions in order to prevent as far as possible the contraction of an upper respiratory infection. Intranasal therapy should be avoided, and the patient must be on his guard against sneezing or otherwise raising the intranasal pressure for fear of forcing secretions through the fracture line into the cranial chamber. Intra-aural examination should be avoided in the case of bleeding or spinal fluid leakage from the ear. The ear should be covered with a sterile dressing and kept dependent so as to encourage external drainage. The majority of cases of spinal fluid leakage, especially from the ear but also from the nose, stop spontaneously. In some instances the drainage will persist for months or years and may eventually require surgical intervention for closure of the fistula. From the standpoint of prevention of infection, the practice of elevating the foot of the bed about 12 inches has been of material help in decreasing the incidence of aspiration pneumonia in patients who are in deep coma. The advantage gained by avoiding the gravitation of vomitus or nasal secretions into the lungs far outweighs the possible disadvantage of increasing the intracranial pressure in lowering the head below the level of the feet. This modified Trendelenburg position need be employed only when the nasopharynx seems to be filling rapidly with mucus

or vomitus and can be resorted to intermittently rather than continuously as the conditions warrant. It is also important in deeply comatose patients to keep them on the side and to alternate the lateral position. In this way the tendency to swallow the tongue is obviated, and secretions tend to run out the angle of the mouth.

TABLE 1.—*Classification of Head Injuries**

		Infection	Subpial Subcortical Intraventricular Venous sinus Petechial
			Meningitis
			Abscess

* Modified from Munro.

A compound depressed fracture is a condition which requires immediate attention in order to avoid the onset of a serious infection. This calls for prompt débridement of devitalized tissues, which may include some of the cerebral cortex as well, if it has been lacerated. This procedure need not leave a bone defect except in cases in which a part of the skull has been badly comminuted, because a block of bone can be removed, molded back almost to its normal contour, boiled and then replaced.

TREATMENT OF INCREASED INTRACRANIAL PRESSURE

The treatment of increased intracranial pressure revolves, of course, about the diagnosis. Those patients who present the classic symptoms of extradural or subdural bleeding, that is a short period of unconsciousness due to concussion, then a lucid interval of minutes or hours, followed by a progressive loss of consciousness, will die almost invariably unless the clot is removed. The second lapse into unconsciousness is due to cerebral compression from the clot. The evolution of the clinical picture is ordinarily much faster in the case of extradural bleeding because the hemorrhage is arterial and requires prompt surgical attention. There are, however, a group of patients who do not present this classic picture and yet harbor a definite clot. In particular the lucid interval is missing for the reason that there is, in addition to the clot, extensive underlying brain damage. In this instance the unconsciousness due to the damage of cerebral tissue per se will merge with the coma due to the increasing intracranial pressure produced by the extradural or subdural clot. These cases present a more difficult problem from the standpoint of diagnosis and constitute the group in which multiple trephine holes are indicated. In this way a clot may be located which may have been overlooked even by careful observation and a life saved if the underlying cerebral damage is not too extensive. The great majority of patients with cranial injuries do not show any alarming degree of increase in intracranial pressure as indicated by lumbar puncture and, more specifically, do not show

a pressure over 200 mm. of water. Those patients who are severely injured and persist in showing an elevated spinal fluid pressure would best be subjected to multiple trephine openings and, in the event that no clot is found, a generous decompression should be made if the brain appears to be under serious pressure. The indications for a decompression are extremely rare, however.

The importance of a thorough neurologic examination of the patient on admission and at frequent intervals thereafter cannot be too forcefully emphasized. The appearance under observation of focal neurologic signs, and particularly a state of progressive loss of consciousness are a clear indication by and large for surgical intervention. On the other hand, an injured person with a cerebral laceration will ordinarily show focal neurologic signs on the first examination, and there will be a tendency in the direction of improvement in the neurologic picture and particularly a progressive return to consciousness. The majority of patients with cortical lacerations or contusions will show bloody spinal fluid but with no alarming elevation of pressure. Patients with minor degrees of subarachnoid bleeding may not present a clinical picture which differs in essentials from those with a moderate degree of concussion. The diagnosis must be made by a lumbar puncture performed within a few days after the injury. Those persons with more marked subarachnoid bleeding show some degree of nuchal rigidity, confusion, dizziness, restlessness, irritability, drowsiness, headache, vomiting and a slight elevation of temperature. These patients are unquestionably made more comfortable by lumbar punctures done usually at twenty-four hour intervals but again at shorter or longer intervals, depending on the amount of blood and the elevation of the spinal fluid pressure.

MANAGEMENT OF DEPRESSED FRACTURES

It is almost axiomatic that every scalp laceration should be carefully examined under sterile precautions before being sutured, to establish the presence or absence of an underlying fracture. This will not be possible, of course, unless the bone is exposed. Further information concerning the nature of the fracture, if

TABLE 2.—*Mortality**

* Modified from Munro.

it appears grossly to be depressed, should be obtained by x-ray examination before the wound is closed. A simple linear fracture should be no matter of concern and no indication for immediate x-ray examination. A compound depressed fracture must be treated promptly in the manner and for the reasons already discussed. Only occasionally will a patient be in such a degree of shock from gross tearing of the brain as to be unfit for any immediate major surgery. If the fracture is not compound, operative treatment is usually not indicated unless the size of the depressed fragment is sufficient to reduce materially the size of the intracranial cavity. The popular opinion that depressed

fragments, per se, may result in epilepsy is not substantiated by recent knowledge of the pathologic response of the brain to trauma. Late epileptic manifestations are due to the formation of a cerebral cicatrix rather than to any irritative effects of a depressed fragment. Glaser and Shafer⁵ have recently reported

Fig. 1 (case 1).—Depressed fracture in left occipitoparietal region.

an eight year follow-up of ninety-one patients with depressed fractures. Their conclusion was that early elevation of the depression did not prevent the development of late sequelae in this series. This corresponds to the experimental observations of Naffziger and Glaser.⁶ The experimental data do not support the usual conception that the continued pressure of a rounded depression on the brain will cause further damage and consequently that elevation should be carried out at any time with or without symptoms. Elevation should be confined to fractures of a fragmented and spiculated nature wherein the dura has been lacerated and the brain traumatized. It is difficult to be specific as to the type of case which does not require elevation because frequently even after careful radiologic examination one is unable to state with any degree of certainty whether the dura and cortex have been grossly injured. Each case is a problem unto itself and requires the judgment and attention of a neurosurgeon. The primary objective in the operative treatment is the débridement of devitalized tissues and the repair of the cranial deformity. If infection is not present, the fragments of bone may be replaced. A delay of more than six hours (approximately) enhances materially the chances of infection. The average traumatic wound, if promptly irrigated and debrided in a thorough fashion, will rarely become infected and requires no drainage. When conditions make it necessary to postpone indefinitely any major surgery, the wound should be carefully cleaned and sutured so as to insure a sterile field for the secondary operation.

USE OF HYPERTONIC SOLUTIONS AND LUMBAR PUNCTURE

One will occasionally see patients so severely injured that death occurs within a few hours or at least within twenty-four hours of the accident. For the most part, these patients show some abnormality

of respiration and more particularly irregularities of rhythm. They ordinarily show signs of marked cerebral irritation and one hesitates in doing anything but the most simple procedures because almost every stimulus seems to throw the injured into a paroxysm of hyperventilation, extensor spasm and extreme restlessness. In any event there is little if anything that can be done to save this type of patient. Some of them, however, in spite of the extremely ominous picture which they present, survive the immediate critical period and gradually return to consciousness after days or weeks. The prolonged period of unconsciousness is due to widespread cerebral lesions in the nature of multiple lacerations and contusions, or petechial hemorrhages or extensive hemorrhage into the brain stem from the vein of Galen, with associated edema and cell damage. It is this group in which the method of repeated lumbar punctures and conservative use of hypertonic solutions has its best clinical application. These measures should not be carried beyond the stage at which increased pressure is no longer demonstrable by lumbar puncture, however. Actually a patient can be brought to a critical state by overenthusiastic dehydration, and a remarkable transformation will occur with administration of generous amounts of fluid, in a manner similar to the effect of dextrose in insulin shock. Afebrile patients should receive about 1,500 cc. of fluid in twenty-four hours, and those with fever proportionately larger amounts.

I have already mentioned that a very large proportion of cases of craniocerebral injury fall into the classi-

Fig. 2 (case 2).—Depressed fracture in right occipital region.

fication of simple uncomplicated concussion and that roentgenograms of the skull need not be taken during the first week. According to Glaser and Blaine,⁷ x-ray films of the skull taken from six months after injury in children to nine months after injury in adults are

as valuable as those taken immediately after injury in determining the presence or absence of fracture. The indications for immediate roentgenograms are few and in this regard I have mentioned compound fractures and fractures through the sinuses as examples. In cases of serious injury in which the diagnosis is some-

Fig. 3 (case 2).—Excised block of bone in place after depressed portion at its center had been remodeled. The small radiopaque bodies are silver clips.

what in doubt, roentgenograms of the skull may be helpful if a shift of the pineal gland can be visualized. The danger of subjecting a patient with a severe head injury to the moving and gyrations necessary for obtaining a series of roentgenograms is obvious. A simple linear fracture of the vault carries no serious import in spite of the aura which has been spun about it by lay persons and in the courtroom. Basilar fractures may be more significant should the sinuses or the cranial nerves be involved.

Lumbar puncture affords a direct approach to the withdrawal of fluid from the cranial cavity. At the same time it is an important diagnostic measure when subarachnoid hemorrhage is suspected. Recent experimental observations suggest that the removal of spinal fluid may minimize certain sequelae such as headache and dizziness. A word of caution is advisable regarding the indiscriminate use of this therapeutic measure. The absence of danger is not unanimously accepted, and in the light of our present knowledge it appears wiser to refrain, if possible, from the use of a lumbar puncture during the first twenty-four hour period. This is based on the assumption that intracranial hemorrhage might be accelerated by the rapid removal of cerebrospinal fluid. It is often not necessary to tap patients with a cerebrospinal fluid leak because the drainage automatically relieves any pressure which might be present, although this is not always the case. There is some danger in reducing the pressure to a point at which there is a reversal of the flow at the site of the fracture and a natural tendency toward introduction of infection into the subarachnoid space. Meningitis of traumatic origin is subject to the same methods of therapy as meningitis of the more common types. The spinal fluid pressure may at times be misleading in the evaluation of the state of the patient. I have noted in several instances that on successive daily punctures the spinal fluid tended gradually to

return to normal, whereas the patient was actually becoming more drowsy. Exploration in these cases revealed a subdural hematoma with decidedly increased intracranial pressure. The discrepancy is probably explained by either an incisural or a foraminal block.

In general it is suggested that sedatives be avoided because of the natural tendency to obscure the picture of progressive somnolence which is so important from the standpoint of diagnosis. Extreme restlessness may precede or accompany a state of progressive stupor due to increasing intracranial pressure, and the tendency to complicate the picture with sedation may make the differentiation difficult. The tendency in particular to sedate intoxicated patients is fraught with grave danger, since one already has to decide whether the hyperactivity and/or somnolence is primarily an alcoholic or a pressure effect. Body restraints usually increase the agitation. The restlessness is not infrequently due to a simple matter such as an overdistended bladder. The bladder can often be emptied by manual expression and a possible infection due to catheterization may be avoided. Restlessness is a rather common accompaniment to subarachnoid hemorrhage and can be controlled in part by repeated lumbar punctures. Morphine in particular is contraindicated because of its depressing effect on the vital centers. Headache can usually be controlled by acetylsalicylic acid. It has been my practice, with patients who are conscious on admission or regain consciousness shortly after, to arouse them for a vocal response at hourly intervals for at least twenty-four hours. In this way it renders it unlikely that a patient will lapse into unconsciousness through the night without this transition having been discovered. This is of particular importance with children and patients who are not hospitalized. A few patients will show considerable elevation of temperature and this is best treated with alcohol sponges, with care being taken not to cool the surface of the body too rapidly. In some instances ice water enemas are more effective. The vital signs are recorded at half hourly intervals for from twenty-four to forty-eight hours in all cases and longer in the more critically injured.

Fig. 4 (case 2).—Visual fields taken fourteen months after the accident.

Patients with head injuries for the most part are not in any notable degree of shock unless there has been excessive loss of blood from a surface laceration or some crushing injury to the bones, or some internal injury. Attention is called to the distinction between so-called primary shock and secondary shock. The former is usually regarded as consisting of a relative lowering of blood volume through vasodilatation, the latter of an absolute lowering of blood volume through

loss of blood or plasma. There is some evidence that trauma to the brain produces a type of shock presenting more nearly the characteristics of primary shock. The state of primary shock is ordinarily very short lived and need be of no special concern. Removal of the cause, replacement of the lost blood volume, rest and heat are the accepted treatment for secondary shock.

It should be stated that mortality figures have been published in several large series of cases and that there is but little statistical discrepancy between them, although the therapy varied in all three. Fay reported 556 cases with a gross mortality rate of 18.2 per cent, Munro 505 personal cases with a mortality of 15.6 per cent and Coleman 453 cases with an 18.5 per cent mortality. Fay is the proponent of rigid dehydration, Munro employs modified dehydration, and Coleman shows a distinct inclination away from both lumbar drainage and dehydration. The objections in general to the use of hypertonic solutions are twofold: the danger of increasing the intracranial bleeding and

sure. More often, however, the changes in vital signs are more subtle, and it is well to be on the lookout for additional criteria in the diagnosis of intracranial bleeding.

REPORT OF ILLUSTRATIVE CASES

CASE 1.—R. C., a white youth aged 15 years, was involved in an automobile accident at the age of 5 years which resulted in a short period of unconsciousness. A laceration was noted in

Fig. 6 (case 3).—Visual fields taken one year after the accident.

the left occipitoparietal region, which was sutured but no roentgenograms were taken.

In his fourteenth year, nine years after the accident, he had four seizures described as tonic in nature and a final episode which consisted solely of a transient numb sensation on the left side of the body beginning in the leg. The neurologic examination at this time was negative. X-ray examination of the skull showed a small depressed fracture (fig. 1) in the left occipital region. An electro-encephalogram showed seizure discharges from the right occipitoparietal area.

This case illustrates the fallacy of the common conception that a depressed fracture is of itself a constant source of posttraumatic epilepsy and should therefore be elevated. The electro-encephalogram confirmed the clinical opinion that the epileptogenic focus was on the opposite side of the brain from the fracture and that the depression was of no importance. This is to

Fig. 5 (case 3).—Multiple fractures of the skull with extension through the cribriform plate and into the frontal sinus.

the almost inevitable secondary rise in spinal fluid pressure which follows the use of hypertonic dextrose. There is some evidence that hypertonic sucrose injection is usually not followed by a secondary rise in pressure. It is also stated that the prolonged administration of hypertonic solutions may have a deleterious effect on the kidneys.

Before the presentation of case histories, emphasis should again be laid on the fact that the classic signs of increasing intracranial pressure, and especially a notable rise in blood pressure with a concomitant increase in pulse pressure, may be a relatively late development in the clinical picture. In fact, if one waits for a striking rise in blood pressure the patient may not survive even if a blood clot is successfully removed. In my experience a tendency to extreme restlessness and increasing stupor has been an earlier and more reliable indicator of increasing intracranial pressure than the vital signs. There are occasional patients who show no striking change in vital signs at all, in spite of there being considerable compression present from a blood clot. It is of course important to tabulate the vital signs and one occasionally sees unequivocal indications of increasing intracranial pres-

Fig. 7 (case 5).—Note the moderate elevation of the blood pressure in a case in which there are two clots, one subdural, the other extradural. A change in the state of consciousness preceded the alteration in the blood pressure by about fourteen hours.

be explained on the basis of a contrecoup injury in the right occipitoparietal cortex.

CASE 2.—R. D., a white man aged 20, was admitted to the hospital on Oct. 25, 1938, about fifteen minutes after having been struck by an automobile. He had been dazed but was not unconscious. There was a laceration of the scalp about 6 cm. long in the right occipital region. The edges of the wound were separated under sterile precautions and some clot was

washed out. When this was being done a small piece of brain tissue measuring a few millimeters floated up. Gross examination of the visual fields revealed a complete left homonymous hemianopia. X-ray examination (fig. 2) showed a depressed fracture at the site of the scalp laceration.

The patient was taken to the operating room. Under local anesthesia the wound was explored and a block of bone removed

Fig. 8.—Course of events following a rise in intracranial pressure according to a conception widely employed and taught in surgical practice. After recovery from the initial shock the intracranial pressure rises and there is a *pari passu* rise in the blood pressure and fall in pulse rate until medullary failure ensues. From this point on the blood pressure falls, the pulse races and shock becomes evident, leading almost inevitably to death. (After Browder, Jefferson, and Meyers, Russell: Behavior of the Systemic Blood Pressure, Pulse Rate and Spinal Fluid Pressure, Arch. Surg. 36: 1 [Jan.] 1938.)

with the depressed portion at its center. The macerated portion of the cerebral cortex was debrided, as was also the dura, which was then closed. The bone flap was sterilized, remolded and replaced into the skull defect (fig. 3).

The importance of careful inspection of scalp lacerations is emphasized by this case. The clean removal of macerated cerebral tissue and dura lessen the chances for the later development of a meningocerebral cicatrix. Roentgenograms taken fifteen months after the injury showed considerable absorption of bone in the block which had been excised and replaced (fig. 3). In spite of the x-ray appearances, the operative area was just as firm as the rest of the skull. Visual fields, (fig. 4) taken at the same time showed a residual left homonymous inferior quadrantic defect.

CASE 3.—J. R., a white man aged 44, was admitted to the Milford Hospital on May 31, 1936, shortly after having been injured in a two car collision. He remained in coma for twelve hours. There was a compound fracture (fig. 5) in the right frontal region extending into the frontal sinus, orbit and cribriform plate of the ethmoid. No evidence of rhinorrhea was noted, although there had been some bleeding from the nose. He was discharged after five weeks.

After three weeks at home he was admitted to the New Haven Hospital because of a sudden elevation of temperature associated with severe headache. Drainage of spinal fluid from the right nostril was noted, and the presence of a meningitis was confirmed, which lasted for about ten weeks. He ultimately made a complete recovery except for anosmia and an almost complete loss of vision (fig. 6) on the right. The rhinorrhea stopped with the subsidence of the meningeal infection and has not recurred in the three intervening years.

A meningeal infection may follow a basilar fracture through the paranasal sinuses as soon as thirty-six hours after the injury and indeed be so fulminating as to be fatal in spite of modern chemotherapy. It should be noted that the cerebrospinal rhinorrhea did not appear until eight weeks after the injury. There is a feeling generally among neurosurgeons that a cerebrospinal rhinorrhea requires a prompt closure of the rent in the dura, in spite of the fact that many of them tend to

stop spontaneously, because there is the constant threat of a meningeal infection.

CASE 4.—H. O., a white man aged 39, was admitted to the New Haven Hospital on Feb. 26, 1939, shortly after being injured in an automobile accident. He was semiconscious on admission, quite noisy and agitated. There was some weakness of the right side of the face and the right arm. In the next few days there seemed to be gradual improvement, and it became apparent that a definite aphasia was present, of a motor type. The initial spinal puncture showed a bloody fluid under increased pressure, but by the eighteenth day the fluid was clear and under normal pressure. In the meantime, however, a low grade papilledema had appeared and roentgenograms of the skull taken at this time showed a shift of the pineal gland to the right, measuring 3 mm. The steady but slow improvement in his speech and mental condition seemed at odds with the development of papilledema and a pineal shift. The diagnosis rested between a laceration in the left frontotemporal region or a subdural clot. Consequently trephine holes were made in the left frontal, temporal and parietal regions on the left, but no blood clot was found. Within six weeks of the time of the accident there had been a complete restitution of function and the patient has remained well.

This case illustrates the contrast in the clinical picture between a cortical laceration and a subdural clot. With the former, one usually finds abnormal neurologic signs on the first examination, unless the lesion is in a silent area, followed by a slow steady improvement, especially in the mental state. The pineal shift and papilledema tended to be misleading. The exploratory operation was undertaken in spite of the apparent improvement in order to make absolutely sure that the speech area was not being subjected to local pressure.

CASE 5.—F. P., a white man aged 55, was struck by a truck on July 20, 1939, and was immediately rendered unconscious. He was semiconscious on arrival in the emergency room about one hour after the accident. Neurologic examination at this time showed no abnormal signs. During the first twenty-four hours there was some improvement in that he seemed aware of his surroundings and took nourishment, but there was no attempt to speak. On the second day he became increasingly drowsy, the right pupil seemed slightly larger than the left, and the pulse and respirations were assuming a slower rate. A spinal puncture showed a bloody fluid under a pressure of

Fig. 9 (case 6).—Vital signs during the thirty-six hours prior to the patient's death. During the first four days after the injury the vital signs maintained a constant level. On the fifth day, about eighteen hours before the patient died, there occurred a moderate elevation of blood pressure and the slowing of the pulse. The patient was in deep coma during the entire illness. At autopsy a large subdural clot was found.

165 mm. of water. His blood pressure gradually rose from a level of about 120 systolic, 70 diastolic to 135 systolic, 60 diastolic. He was taken to the operating room, where a trephine opening was first made in the left temporal region because of the absence of spontaneous speech in the lucid interval (first twenty-four hours). When the dura was opened

a clot was encountered and a large quantity of clotted and unclotted blood was evacuated. A trephine hole was then made in the right temporal region and on opening the dura a small amount of thin yellow fluid escaped. The burr hole was then enlarged and toward the upper margin of the exposure the edge of an extradural clot was seen which proved to be of considerable size. This clot was also evacuated. There was rather prompt improvement following the operation.

The progressive tendency toward a stuporous state and the lack of return of spontaneous speech were in sharp contrast to the events in case 4, in which a diagnosis of cortical laceration was made. The left side was explored first because of the aphasia. The right side was also opened because the right pupil tended to be somewhat larger than the left and because of the fact that bilateral subdural hematomas are fairly common. The combination of a large subdural clot on one side and an extensive extradural clot on the other is rather unusual. Attention is called to the lack of striking changes in the vital signs (fig. 7) and to the slight elevation in spinal fluid pressure in spite of the amount of clot found. Figure 8 illustrates the course of events in a hypothetical case following a rapid rise in intracranial pressure according to a conception widely employed and taught. This alarming degree of alteration in the vital signs is not often seen, however, and one must be prepared to act on more subtle changes in the vital signs plus a tendency toward increasing somnolence.

CASE 6.—F B., a white man aged 22, was brought into the hospital on June 17, 1934, about a half hour after having been struck by an automobile and instantly rendered unconscious. He was in deep coma on admission and there was obvious respiratory distress. The pupils were fixed, the right being semidilated and the left fully dilated. There developed in the next twenty-four hours a flaccid weakness of the right arm and leg. On the third day the right pupil had returned to its normal size but the left pupil was still widely dilated and the eyeball was practically fixed as the result of oculomotor paralysis. The spinal fluid on the fourth day was bloody and under a pressure of 130 mm. of water, a drop of 120 points from the pressure reading taken forty-eight hours previously. His temperature ranged between 101 and 104, his respirations were irregular and the pulse varied between 100 and 140. The blood pressure remained between 100 systolic, 70 diastolic and 130 systolic, 80 diastolic. There was a marked degree of restlessness associated with a constant state of unconsciousness. A left lower lobe pneumonia was noted on the fourth day, and on the following day he died. At postmortem a large subdural clot was found on the left side. In addition there were lacerations of the basilar surface of the left frontal and temporal lobes and multiple subcortical petechial hemorrhages.

There were multiple brain injuries in this case, and the subdural hematoma was only one factor in the production of the clinical picture depicted. It is in just such an instance, in which the classic signs and symptoms of subdural hematoma are lacking because of additional injuries, that multiple exploratory trephine openings are indicated. Certainly if the subdural clot had been found and removed, the chances for survival would have been better. Attention is again called to the fact that the vital signs were fairly constant and within normal limits for the first four days, and there then followed in the few hours preceding the patient's death a moderate rise in blood pressure (fig. 9). A third nerve (oculomotor) paralysis which follows a head injury may be due either to a contusion or laceration of the nerve or, as in this case, to compression from a blood clot.

New Haven Hospital.

CRANIAL AND INTRACRANIAL COMPLICATIONS OF ACUTE FRONTAL SINUSITIS

PAUL C. BUCY, M.D.

CHICAGO
AND

W. TRACY HAVERFIELD, M.D.

JACKSONVILLE, FLA.

The most common complications of acute frontal sinusitis, particularly that which follows swimming, are abscess of the frontal lobe and osteomyelitis of the frontal bone.¹ Within recent years the rhinologists and neurosurgeons have adopted more or less successful methods of dealing with these complications. Nevertheless the problems presented by these complications can by no means be regarded as settled. The most crying needs are for the adoption, if possible, of prophylactic measures that will limit the infection to the sinus and prevent the development of these and similar complications, and for the dissemination of knowledge

Fig. 1 (case 1, July 2, 1939).—Extensive osteomyelitis involving the entire right half of the frontal bone.

regarding this condition beyond the confines of these two most interested groups of specialists to the entire medical profession.

As a basis for this discussion we have chosen three cases of fulminating frontal sinusitis complicated by cranial or intracranial infections, and one case of osteomyelitis of the frontal bone and intracerebral abscess of different origin. Typically, all three cases of sinusitis occurred in adolescents and all followed swimming.

REPORT OF CASES

CASE 1.—R. C., 16 year old boy; swimming April 17, 1939; almost immediate development of right frontal headache, edema of right side of forehead and swelling of eyelids; April 21 stiff neck; May 16 left-sided convulsions; diplopia; headache and vomiting; July 1 comatose; admitted July 2; right frontal sinusitis, osteomyelitis of frontal bone, abscess right frontal lobe; repeated operations; recovery.

R. C., a boy aged 16 years, was first admitted to the University of Chicago Clinics Sunday, July 2, 1939, at 11:30 a. m. in a stuporous condition. According to his mother, he went

From the Division of Neurosurgery of the University of Chicago Clinics.

Read before the Chicago Laryngological and Otolological Society, Jan. 8, 1940.

1. We are well aware that there are other less common complications of frontal sinusitis, such as subdural abscess, sinus thrombosis and meningitis, and also that similar complications may arise from chronic frontal sinusitis particularly following surgical intervention. However, only confusion and misunderstanding can arise from a discussion of the complications of chronic and acute sinusitis together in spite of their similarity, and we have chosen to refer only to the latter.

swimming April 17, 1939. The following day he complained of a right frontal headache; within the next twenty-four hours the pain became very severe, and a swelling appeared in the center of the forehead which soon spread to both upper eyelids and to the right half of the forehead. Local hot applications and some "pills" were prescribed but the condition grew steadily

Fig. 2 (case 1, July 2, 1939).—Lateral view. Osteomyelitis extends back to the coronal suture.

worse. By April 21 he was also complaining of stiffness of his neck. On the 26th he was admitted to another hospital, where he remained until May 8. During this period an incision was made in the right upper eyelid and an amber fluid drained. Following this incision the swelling of the left upper eyelid disappeared but the right eye remained closed.

May 16, approximately one month after the onset, he began to have localized clonic convulsive seizures involving the left side of the face and left arm. Diplopia was present whenever the right eye was held open, and the headache and stiffness of the neck continued. June 5 roentgenograms taken by the family physician were said to have shown osteomyelitis of the right frontal bone. June 20 he suddenly lost consciousness and subsequently vomited. July 1 he became drowsy and at noon lapsed

Fig. 3 (case 1, July 2, 1939).—Taken after aspiration of the abscess and the introduction of 5 cc. of colloidal thorium dioxide. The abscess is flattened after evacuation but is obviously not in contact with the dura mater or skull at any point. The opening in the skull through which the pus was removed is seen in the posterosuperior frontal region.

into a deep "sleep" from which he could not be roused. He was admitted to this hospital the following day in a semicomatose state.

Examination.—The patient was poorly nourished and emaciated and in a semicomatose condition. The temperature was

100 F. (rectally), pulse rate 72 and respiratory rate 24 per minute. The blood pressure was 118 systolic, 70 diastolic. On palpation the entire right half of the frontal bone was found to be roughened and there were small fluctuant swellings beneath the scalp. There was ptosis of the right upper eyelid. The pupils were equal but only the left reacted to light. There was bilateral papilledema with many hemorrhages about the disks. There was definite left facial weakness and there seemed to be left hemiparesis. There was some atrophy of the small muscles of the left hand. The tendon reflexes were all present possibly slightly more active on the right side. Babinski's sign was present on the left.

He had leukocytosis with a count of 13,600. The blood contained 12 Gm. of hemoglobin and 4,620,000 red blood cells per cubic millimeter.

Roentgenograms of the skull revealed massive osteomyelitis of the entire right half of the frontal bone from the supra-orbital ridge to the coronal suture, which extended a slight distance across the midline to the left side (figs. 1 and 2).

It seemed obvious that the boy was suffering from an abscess of the right frontal lobe of the brain and extensive osteomyelitis of the right frontal bone, which had developed from a right frontal sinusitis.

Fig. 4 (case 1).—The entire right half of the frontal bone including the supra-orbital ridge and a small amount of bone to the left of the midline has been removed.

First Operation.—Relief from increased intracranial pressure being imperative, he was taken to the operating room. A short incision was made at approximately the level of the coronal suture on the right side and a trephine opening made in the underlying bone was enlarged to 2.5 by 4 cm. On incision the dura mater was found to be densely adherent to the underlying cerebral cortex. Immediately beneath the surface of the cortex was a superficial abscess from which 30 cc. of pus was evacuated. It was obvious that there was additional pathologic change. A blunt needle was inserted and at a distance of 4 cm. it encountered a second abscess from which 45 cc. of thin yellowish hemorrhagic pus was evacuated. Five cc. of colloidal thorium dioxide was injected into the abscess cavity in order that its size and position might be followed with x-rays (fig. 3). The wound was closed. Cultures of the pus all revealed hemolytic *Staphylococcus aureus*.

Almost immediately after the operation the patient roused from his stupor, responded and became quite restless. On examination he appeared to be totally blind.

Second Operation.—By July 6 his condition had improved so much that the necessary surgical treatment was undertaken. The old incision was extended medially and laterally within the hair line, and the scalp was reflected downward off the right frontal bone. There were much pus and many small bony sequestrums beneath the galea and the fragmented periosteum. The entire right half of the frontal bone was eroded, fenestrated and extensively infected. All of this involved bone, to the left beyond the midline, back to the coronal suture and laterally

beneath the temporal muscle, was removed with a rongeur (fig. 4). A large circular incision was made in the dura mater overlying the abscess to allow it to herniate out of the brain.

The patient soon became normally alert and cooperative. The left hemiparesis disappeared. July 13 70 cc. of pus was aspirated from the abscess and an additional 5 cc. of colloidal thorium dioxide was injected into it. The position of the abscess was then followed by daily roentgenograms. It was seen to shift laterally gradually and July 15 a third operation was undertaken.

Third Operation.—The old incision was reopened and the scalp was reflected forward. The encapsulated abscess projected about 2 cm. beyond the skull and was covered by a thin layer of necrotic cerebral tissue. It seemed possible to enucleate this abscess. However, the upper part of the abscess was unex-

Fig. 5 (case 2).—Four months after extirpation of osteomyelitis of right half of frontal bone.

pectedly thin and ruptured, releasing a large quantity of pus. The abscess cavity was then drained and the wound closed about the drains.

We were delighted to discover on the following day that the boy had some vision in his left eye. His condition and the vision gradually improved. He was discharged from the hospital September 5, at which time he was able to read ordinary newspaper print with his left eye although vision was largely limited to the nasal half of the field and he could only perceive light with the right eye. Ocular movements were full in all directions. Both pupils reacted to light.

He has since been followed in the outpatient department. His general condition has steadily improved although there has been little, if any, change in his vision since he was discharged from the hospital, and there has been no relapse except that two small sequestrums were removed from the region of the supra-orbital ridge on November 11. He is now anxious to return to school.

There is a considerable deformity of the right frontal region, which will eventually be corrected.

The disease in this instance was by far the most severe. There can be no question but that its severity was very materially increased by a marked delay in the institution of appropriate treatment, a delay of over two months after the first manifestations of intracranial

Fig. 6 (case 2, Sept. 8, 1939).—Osteomyelitis has invaded the right half of the frontal bone along the two main diploic venous channels. One extends directly upward from the sinus, the other extends upward from the malar process and then curves medially.

involvement (a stiff neck), of over six weeks after the first evidence of cerebral involvement (the convulsions) and of almost a month after extensive osteomyelitis of the skull was demonstrated with the x-rays.

This case presents the typical clinical course of those in which an intracerebral abscess develops from the ear or from the paranasal sinuses. The intracranial infection is heralded by the general manifestations of increasing infection. The temperature rises, there is an increas-

Fig. 7 (case 2).—Practically all of the right half of the frontal bone has been removed.

ing leukocytosis, the patient is obviously sicker—"toxic" is the word commonly applied. He may have a chill and almost invariably there is rigidity of the neck. This sudden exacerbation is usually of short duration, often only from one to three days. With the subsequent improvement the patient, his family and the doctor all heave an unjustified sigh of relief. After a variable

period of days or weeks, depending on the rapidity of the growth of the abscess, signs of cerebral or cerebellar involvement, as the case may be, appear. At this second stage the usual evidences of infection, fever, tachycardia and leukocytosis, are commonly either minimal or

Fig. 8 (case 3).—The trephine opening is seen in the left frontal region. The abscess, now collapsed, is shown by the colloidal thorium dioxide which has been injected into it. There is no osteomyelitis present.

absent. Either simultaneously with or shortly after the appearance of this second stage evidences of increasing intracranial tension, headache, vomiting and choking of the optic disks, develop. If adequate treatment directed

Fig. 9 (case 3).—Lateral view showing the location of abscess.

toward the abscess itself has not already been instituted it now becomes imperative if the more serious sequelae of blindness, stupor, coma and death are to be avoided.

This course of events is so constant and so significant as to diagnosis and treatment that it deserves to be far better known. It may not always be possible to prevent the development of abscesses of the brain, but their presence can usually be recognized and appropriate treatment instituted early enough to prevent death or blindness if one is merely familiar with this train of events.

The second case of our series presents a surprising similarity to the first except that, fortunately, the extending infection was confined to the frontal bone.

CASE 2.—F. D., 12 year old girl; dived in water feet first Aug. 6, 1939; immediate pain at root of nose; August 13 swelling right eye; August 26 roentgenograms revealed osteomyelitis; admitted September 8; immediate radical excision of osteomyelitis; rapid recovery.

F. D., a girl aged 12 years, was referred to the University of Chicago Clinics by Dr. M. M. Hipskind of Chicago.

Aug. 6, 1939, she had gone swimming. She dived in feet first and immediately thereafter complained to her father of pain at the root of the nose. August 8 she complained of nasal obstruction. On the 10th she was sleepy and had a low grade fever. On the 12th she complained of pain over the right frontal sinus and on the 13th a swelling appeared at the inner angle of the right eye and grew progressively worse until the eye was swollen shut. The oral temperature was 101.6 F. The following day both eyes were swollen shut. Roentgenograms taken August 18 revealed some clouding of all of the paranasal

Fig. 10.—Normal skull of a boy of 10 years. The frontal diploic vein is most developed on the left side, while the anterior temporal veins are well seen on both sides. Compare with the course of the osteomyelitis in case 2, figure 5.

sinuses. Those made August 26 revealed an osteomyelitis of the right supra-orbital ridge, while the films exposed August 29 and September 6 revealed a gradual extension of the osteomyelitic process.

She was admitted to the University of Chicago Clinics September 8. Examination revealed edema of the right frontal region with several elevated fluctuant areas. The right upper eyelid was swollen and inflamed. There was paralysis of the right superior rectus muscle. The optic disks were normal in

Fig. 11 (case 4).—Area of osteomyelitis along the course of the left anterior temporal diploic vein (to be compared with fig. 10).

appearance. No rigidity of the neck or other abnormal neurologic feature was noted. The temperature was 37.8 C. (100 F.), pulse rate 100 and respiratory rate 24. The blood examination revealed 6,200 leukocytes, 4,550,000 erythrocytes and 90 per cent hemoglobin.

Roentgenograms of the skull revealed two areas of osteomyelitis extending upward into the right frontal bone from the

frontal sinus. One was just lateral to the midline and followed the right frontal diploic vein. The other was higher and farther lateral and followed the anterior temporal diploic vein (fig. 6).

A diagnosis of osteomyelitis of the frontal bone on the right side was made, and the patient was taken to the operating room.

Operation.—September 8 a curved incision was made just back of the hair line, and the scalp was reflected downward off the right frontal bone. There was a small amount of pus and granulation tissue between the scalp and the bone in several places. The bone was roughened and in several places eroded through to the dura mater. Practically all of the right half of the frontal bone, including the walls of the frontal sinus and the supra-orbital ridge and extending back to the coronal suture, was removed before healthy bone was reached (fig. 7). There was a moderate-sized extradural collection of pus and granulation tissue beneath the more medial area of osteomyelitis. Two soft rubber drains were inserted beneath the scalp and the wound was closed.

Postoperative Course.—She made a rapid recovery and was discharged September 25. Except for the removal of a small localized area of infected bone overlooked at the first operation and subsequently demonstrated by x-rays she has remained in perfect health. There is only a very slight deformity in the right frontal region (fig. 5). Roentgenograms of the skull made Jan. 2, 1940, revealed definite evidence of beginning of regeneration of bone at the site of the defect. This regenerated bone could also be palpated. To date, June 17, 1940, this child has remained in perfect health and regeneration of the bone is continuing rapidly.

In contrast with the first case there was far less delay here. However, the avoidance of a severe intracranial infection must be attributed more to good fortune than to prompt action; for the month that elapsed between the onset of the sinus infection early in August and the removal of the infected bone in September was more than sufficient, as case 1 adequately shows, for the cerebrum to have been invaded.

Whereas acute fulminating sinusitis in the second case was complicated by osteomyelitis of the frontal bone without an associated brain abscess, the third case presents a brain abscess without any osteomyelitis.

CASE 3.—*M. B., 14 year old boy; swimming June 11, 1939; almost immediate severe left frontal headache; subsequent swelling left upper eyelid; continuous headaches; July 4 generalized convulsion; persistent vomiting; September 10 dizziness, diplopia, blurred vision; admitted September 20; right frontal lobe abscess; drained; recovered.*

M. B., a boy aged 14 years, was referred to the University of Chicago Clinics by Dr. Thomas Krause of Rockford, Ill.

June 11, 1939, he went swimming and got some water in his nose. That night a severe headache developed in the left frontal region. The headaches continued and one week later the left upper eyelid became swollen. A diagnosis of frontal sinusitis was made, but on endonasal drainage no pus was obtained. Subsequently the left upper eyelid was incised and there was free drainage for ten days, after which the incision healed spontaneously. The headaches, however, continued, and the pain radiated around the head and down into the neck. July 4 he became unconscious, had a generalized convulsion and later vomited. Subsequently vomiting recurred, gradually increasing in frequency. The headaches gradually shifted to the right frontal region. About September 10 he began to have attacks of dizziness and diplopia and the vision became blurred. At no time did he have more than 1 degree F. of fever.

He first came under the care of Dr. Krause September 17, when he was admitted to the Rockford Hospital. At that time ophthalmoscopic examination revealed severe papilledema bilaterally. On lumbar puncture the spinal fluid pressure was 40 mm. of mercury. The fluid contained 59 cells per cubic millimeter, 55 per cent of which were polymorphonuclear leukocytes and 40 per cent lymphocytes. The blood contained 11,300 white blood cells. He was transferred to the University of Chicago Clinics September 20.

Examination.—The temperature was 37.6 C. (99.7 F.), pulse rate 108, respiratory rate 22 and blood pressure 96 systolic, 56 diastolic. The boy was thin and underdeveloped for his age. The left upper eyelid was slightly swollen and contained a well healed scar. No abnormality of the heart, lungs or abdomen could be detected. There was marked bilateral papilledema with numerous hemorrhages and exudates. The visual fields were full to gross testing. Ocular movements were full. The left pupil was slightly larger than the right and both reacted sluggishly to light. There was a slight left lower facial weakness, most marked on smiling. On phonation the soft palate moved upward and to the right. Muscular strength, coordination and sensation were intact in all four extremities. The tendon reflexes were all active, though slightly more so on the left side. The abdominal reflexes were less active on the left, and Babinski's sign could at times be elicited on the left side. Station and gait were normal but he was more awkward on attempting to hop on the left leg. There was slight rigidity of the neck.

Examination of the blood revealed 10,900 white blood cells, 16 Gm. of hemoglobin and 5,300,000 red blood cells (all values possibly attributable to dehydration). The Wassermann and Kahn tests on the blood were negative. Roentgenograms of the skull revealed no evidence of sinusitis or osteomyelitis, but there was a moderate separation of the sutures of the cranial vault.

Abscess of the right frontal lobe secondary to left frontal sinusitis was diagnosed.

First Operation.—September 21 an incision was made just posterior to the hair line in the right frontal region. A trephine opening was made and enlarged with a rongeur to 3 cm. in diameter. A stellate incision was made in the dura mater, and the subdural space was packed with gauze. A blunt needle encountered a thick-walled abscess at a depth of 3 cm. from which 40 cc. of greenish pus was evacuated. A small quantity of colloidal thorium dioxide was injected in order that we might follow the abscess roentgenographically (figs. 8 and 9).

The patient was subsequently relieved of the headaches and vomiting. The subdural packing was removed in two days.

Second Operation.—September 27 the wound was reopened. The necrotic cerebral tissue overlying the abscess was removed with suction, disclosing the abscess 1 cm. beneath the surface of the cortex. The abscess was incised and evacuated. A firm rubber drain 1 cm. in diameter was inserted, and the remainder of the cavity was packed with gauze.

The patient's condition gradually improved and he was discharged from the hospital in excellent condition November 25.

It is doubtful in this case whether an accurate localizing diagnosis could have been made at an earlier date without the assistance of pneumo-encephalography.² Yet had relief of the increased intracranial pressure been much longer delayed, serious impairment of vision would most certainly have resulted.

Although the frontal lobe abscess is usually found on the same side as the frontal sinusitis; that such is not invariably the case is well shown by the example just presented. A somewhat similar spread of the infection by the cranial and intracranial venous system is also illustrated by case 4, to be presented later.

PATHWAY OF EXTENSION

Case 1 was much too far advanced when we first saw the patient to give any clue as to how the infection had spread from the sinus, but cases 2 and 3 are far more instructive.

It has long been recognized that there are several potential avenues by which the infectious organisms may invade the frontal bone and the intracranial cavity. Direct spread by way of the diploic spaces was recognized early by Turner³ and subsequently by numerous

2. Although practically no observations have been reported relative to the value of electro-encephalography in the localization of cerebral abscesses, it would seem more than likely that this procedure may prove of very great value in the diagnosis of these conditions in which accurate localization is too often difficult.

3. Turner, A. L.: The Operative Treatment of Chronic Suppuration in the Frontal Sinus, *Edinburgh M. J.* 17: 239-257, 1905.

other writers. Spread along the perineural sheaths of the olfactory nerves, surely a rare channel, has been cited by Courville and Rosenwold.⁴ The pathway most commonly indicted is the diploic veins which spread upward from the region of the frontal sinus (Courville and Rosenwold,⁴ Furstenberg,⁵ Mosher,⁶ Mosher and Judd,⁷ Behrens⁸). We agree with these authors that these venous channels are usually responsible and with Courville⁹ that spread of infection from the ears and other areas of the skull is commonly by a similar route.

Spreading upward from the region of the frontal sinus into the frontal bone and to emissary veins which penetrate to the superior longitudinal sinus or its immediate tributaries are two diploic veins, the frontal and the anterior temporal. These are well shown in the roentgenogram of a child's skull in which no infection existed (fig. 10). Although the configuration of these diploic veins varies from case to case they constantly occupy the same general position. The frontal diploic vein passes upward from the region of the frontal sinus a short distance lateral to the midline of the skull. The anterior temporal diploic vein passes upward from the region of the malar process, then curves medially parallel to and a short distance anterior to the coronal suture. How either one or both of these channels act as pathways for the infection is beautifully shown in the roentgenograms from case 2 (fig. 5). There the process has been caught before the infected areas which have developed along these two channels have coalesced, and each is clearly shown.

It seems safe to assume that osteomyelitis develops only when thrombosis occurs and that in some instances infection may pass through these veins into the superior longitudinal sinus and thence, retrograde, into the ipsilateral or contralateral cerebral hemisphere without the venous wall becoming infected. In such a case a brain abscess appears without the development of an intervening osteomyelitis, as in case 3.

In case 4, which also illustrates these points, both the osteomyelitis and an abscess developed. This, like case 3, clearly shows that the abscess may lie in either hemisphere regardless of the side of either the sinusitis or the osteomyelitis. And it further demonstrates that an infection spread by this means from an osteomyelitis of the frontal bone need not necessarily lodge in the usual site, well forward in the frontal lobe, but may involve more posterior parts of the hemisphere.

CASE 4.—M. G., 3 year old girl; July 26, 1936, left subtemporal abscess; Sept. 6, 1936, osteomyelitis, along left anterior temporal diploic vein, excised; September 15 right posterior frontal lobe abscess; drained; recovered.

M. G., a girl aged 3 years, was referred by Dr. Frank Greer, of Chicago, to the University of Chicago Clinics. She was admitted July 29, 1936. Two weeks before admission a swelling had developed in the left temporal fossa, apparently secondary to a sty on the left upper eyelid and a fall in which the region of the left eye was injured. The only other complaints were a low grade fever (not over 102 F.), a temporary left external rectus palsy and irritability.

First Operation.—Examination, including x-ray study of the skull, revealed only a fluctuant swelling in the right temple. This was incised disclosing an abscess beneath the temporal muscle which healed promptly after it was drained. Cultures showed hemolytic *Staphylococcus aureus*.

During the postoperative period it was thought on several occasions that there was slight blurring of the margins and elevation of the optic disks. However, as there were no other abnormalities, as the general condition remained excellent and the disks did not show any progressive changes she was discharged August 26, after rather prolonged observation.

Soon thereafter a small swelling developed beneath the scalp just at the hair line in the left frontal region. She was readmitted September 6. Roentgenograms of the skull revealed an unquestionable area of osteomyelitis in the left frontal bone along the course of the anterior temporal diploic vein (fig. 11). This extended up to the region of the superior sagittal sinus. Physical and neurologic examinations, except for the swelling in the frontal region and the healed temporal scar, revealed nothing abnormal. The optic disks were unchanged.

Second Operation.—September 8 the osteomyelitic area was completely removed. She continued well until September 13, when chickenpox developed.

September 15 she complained of headache and vomited. Examination revealed definite bilateral papilledema and left hemiparesis with increased tendon reflexes and Babinski's sign on the left but no demonstrable sensory changes.

Third Operation.—A diagnosis of a brain abscess in the right posterior frontal region was made. A trephine opening was made in this region September 16, and 30 cc. of pus was aspirated from an abscess which was encountered at a depth of 6 cm. Cultures showed hemolytic *Staphylococcus aureus*.

Subsequently the abscess was aspirated repeatedly but finally had to be drained. After several operations the infection was finally eradicated. Although a moderate hemiparesis persists, she continues well according to information recently received from Dr. Claude C. Coleman, of Richmond, Va., and her father.

This case illustrates with almost diagrammatic clarity the pathway followed by the infection. From the sty on the eyelid it spread, perhaps as the result of trauma, to beneath the left temporal muscle; there it produced an abscess and then invaded an emissary vein and spread to the anterior temporal diploic vein, part of which became thrombosed, giving rise to an area of osteomyelitis just anterior to the coronal suture (fig. 11). After a brief interruption it continued onward into the superior longitudinal sinus, backward to and down one of the rolandic veins, and was deposited in the substance of the opposite (right) cerebral hemisphere; in this nidus it developed into a localized cerebral abscess.

It is obvious from a study of these cases that any procedure aimed at the prevention of a cerebral abscess must not only eradicate the focus of infection but also interrupt the venous channels which form an open and continuous pipeline into the cerebral substance.

PREVENTION

Of all the problems arising from acute frontal sinusitis, that of prevention is at the same time the most pressing, the least adequately understood and the most difficult. It divides itself into two phases: (1) prevention of the sinusitis and (2) treatment of the sinusitis, once it develops, adequate to prevent the appearance of complications.

From our own experience and from a review of the literature we agree with Mosher¹⁰ that "Our worst cases of frontal sinus infection and osteomyelitis have followed swimming." This is due, as Taylor¹¹ has

pointed out, to two factors: "Foreign bacteria may gain entrance to the deeper portions of the nasal apparatus and the conjoined structures, or bacteria normally and constantly in this region may be allowed, by a lowered resistance on the part of the swimmer, to multiply to pathologic proportions."

Unfortunately this phase of the problem cannot be solved by the very best of bacteriologic control of swimming places by public health authorities. They cannot sterilize the swimmer's own nasal passages. It is to be hoped that educational efforts by members of the profession such as those by Taylor¹¹ and by Taylor and Dyrenforth¹² will encourage the teaching of proper breathing, the use of suitable devices, such as nose clips and ear plugs, while swimming, and the avoidance of chilling. Although such education may ultimately be expected to reduce the incidence of sinus infections, it is far too much to expect that the problem can be abolished by such means. "The old swimmin' hole" is not always conducive to the care requisite to these needs, nor are swimming and diving responsible for all cases of fulminating frontal sinusitis.

We turn then to the problem of the limitation of the infection to the sinus. We realize that not being rhinologists we tread here on unfamiliar ground, perhaps unwanted. In the rhinologic literature, particularly the standard textbooks, one finds little help. Most authorities appear content to "shut the door after the horse has been stolen" and advise treatment which could be adequate to drain the infected sinus only after evidence of osteomyelitis, meningitis or an abscess has appeared (Ballenger and Ballenger,¹³ Lederer,¹⁴ Turner,¹⁵ Thomson and Negus¹⁶). Others¹⁷ largely ignore the problem. Obviously treatment directed toward eradicating the infection in the sinus is, in the main, useless once the infection has spread to the frontal bone, the brain or the meninges. If the production of adequate surgical drainage of the sinus is ever indicated, if it is of any value in preventing the development of cranial and intracranial infection, it obviously must be applied, if it is to be effective, before the infection has spread.

It appears to us that in fulminating cases of frontal sinusitis associated with pain, tenderness, local swelling and fever, particularly those cases which follow swimming, adequate external drainage of the infected sinus becomes imperative on making the diagnosis. In taking this position we appear to have the support of Hastings,¹⁸ Adson and Hempstead,¹⁹ Williams and Heilman²⁰ and certainly of the rhinologic profession's first authority on the subject, Dan McKenzie.²¹ We wish to emphasize two qualifications to our statement.

First, we are referring only to acute fulminating frontal sinusitis, particularly those instances that follow

swimming, and do not wish to support the position apparently taken by Woodward,²² who seems to advise external surgical drainage for all cases, both acute and chronic, of frontal sinusitis.

Second, we do not presume to tell the rhinologists what constitutes adequate external drainage of the infected sinus. It does appear to us, however, that endonasal drainage is wholly inadequate for this purpose. It is too much to expect that the nasofrontal duct, which is "not infrequently . . . constricted and sinuous due to the encroachment of some of the frontal anterior ethmoidal cells" (Jackson, Coates and Jackson,¹⁷ p. 25) and always edematous and partly or completely obliterated as a result of the infection, will provide adequate drainage, even though partial resection of the middle turbinate, shrinkage of the mucosa or other endonasal procedures are also carried out. We would emphasize with Adson and Hempstead¹⁹ that "It is obvious that early drainage of a suppurating frontal sinus will preclude extension of the infection to the frontal bone and brain." But such drainage must be prompt, must be obtained before any extension of the infection beyond the sinus has occurred. And in these acute infections which follow swimming such extension occurs amazingly early, as our cases demonstrate.

It may be objected that such early surgical intervention in the presence of a fulminating infection will only serve to spread the infection and prevent its being localized. We would call attention to the fact that one is dealing here with an infection that does not tend toward spontaneous localization and spreads because it is confined to a bony cavity, the sinus, without adequate drainage. It is reasonable to suppose, therefore, that drainage may prevent the invasion of the venous system by the infection, which is present in the sinus under pressure, by providing it with an adequate channel of egress, which will relieve the pressure and provide for the removal of infectious material. We would further call attention to the fact that in each of the three cases recorded here the infection spread spontaneously and without any intervening or precipitating surgical procedures, and furthermore that it spread very early. Accordingly it is not to be expected that drainage of the sinus will be effective unless performed early, before any dissemination of the infection has begun, or that it will be able to control the infection in all cases irrespective of the virulence of the infectious agent or the patient's condition. Such would be contrary to all other therapeutic experiences.

TREATMENT OF OSTEOMYELITIS

McKenzie's original dictum that "once progressive osteomyelitis has set in, the only chance of saving the patient lies in the immediate and entire removal of the diseased bone"²¹ has at last been accepted by practically all neurologic surgeons (Fincher²³) and most rhinologists (Furstenberg,⁵ Mosher,⁶ Mosher and Judd,⁷ Mosher,¹⁰ Woodward,²² Skillern,²⁴ McKinney,²⁵ Wilensky,²⁶ McKenzie²⁷). However, some still persist in

a more conservative attitude, insisting that osteomyelitis of the skull should be treated like osteomyelitis anywhere else in the body,²⁸ that is by drainage and the removal of sequestrums when they form (Hastings,¹⁸ Williams and Heilman,²⁰ Skillern²⁹). This view of cranial osteomyelitis completely overlooks the important and essential differences between such infection here and in other bones of the body. As both Fincher²³ and Adson and Hempstead¹⁹ have pointed out, osteomyelitis of the skull either untreated or inadequately treated commonly results in abscesses within the brain. Accordingly the only defensible treatment of osteomyelitis of the skull is early diagnosis and complete removal of all infected bone with interruption of the venous channels in the bone which bear the infection inward.

It has been maintained by some²⁹ that there are two types of osteomyelitis of the frontal bone secondary to frontal sinusitis: (1) a localized and (2) a diffuse

And that raises the question of how to recognize the development of this condition. As Mosher has repeatedly pointed out, and as the general surgeons and roentgenologists have known for many years, osteomyelitis does not give roentgenographic evidence of its presence for at least ten to fourteen days after the onset. Thus if the condition is to be recognized and treated early it becomes impossible to wait for or rely on the roentgenograms. Fortunately there is one constant and pathognomonic sign of osteomyelitis of the frontal bone, an edema of the forehead extending upward from the supra-orbital ridge. Such a development is positive in its implications both as to diagnosis and as to treatment.

How the operation is to be performed and what incision is to be used are matters of minor importance. Each operator should choose that incision and those instruments best fitted to his hands, although like most other neurosurgeons we admit to an unconquerable dis-

taste for and fear of the mallet and chisel. The only requirements are that the infected bone be entirely removed without lacerating the dura mater, with a minimum of trauma to other tissues and with as little hemorrhage as possible.

TREATMENT OF BRAIN ABSCESS

Each neurosurgeon has his own special technic for dealing with abscesses of the brain. Recently we have presented ours.³⁰ It undoubtedly has no great advantages over any other but in our hands has proved reasonably successful. Briefly it is as follows: The abscess having been localized, a trephine opening is made in the skull overlying it and enlarged to approximately 3 cm. in diameter. A stellate incision is made in the exposed dura mater, and the subdural space about the margins of the opening is packed with self-sedged gauze soaked in a weak solution of iodine

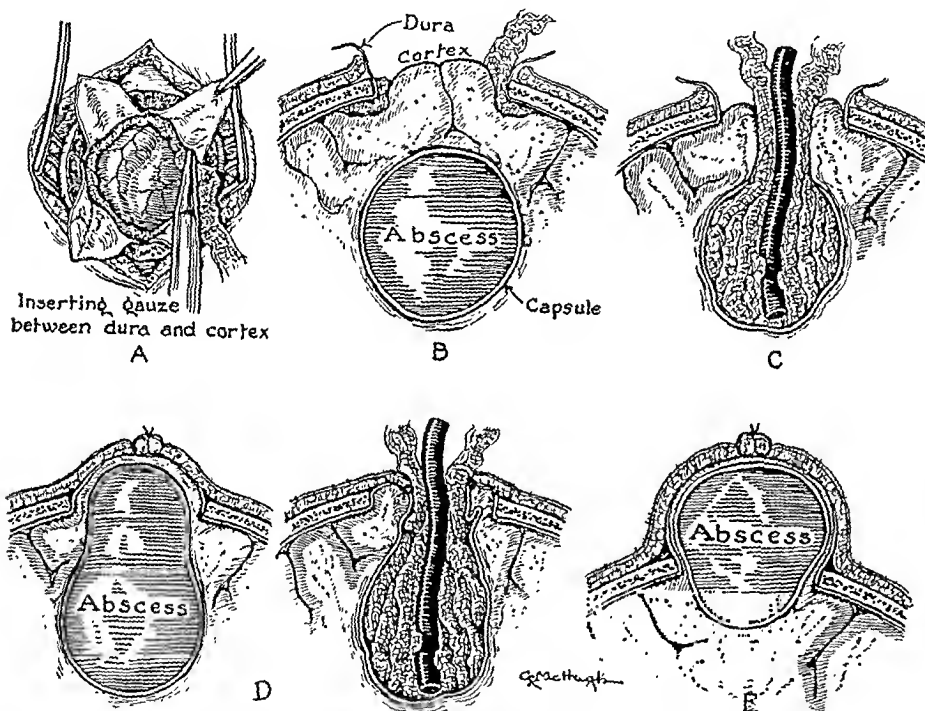

Fig. 12.—Treatment of brain abscess. First stage (A and B): A trephine opening is made over the abscess and enlarged to 3 cm. in diameter. The dura mater is incised and the subdural space is packed with self-sedged gauze soaked in a weak solution of iodine. The gauze is removed after two days.

Second stage (C): The usual appearance. The cortex overlying the abscess is removed and the abscess is evacuated, drained and packed. (D) When the abscess is partially herniated it may be marsupialized. (E) Occasionally it will be found to have herniated out of the skull and can then be removed in toto.

spreading type. We entertain serious doubts as to whether the slowly progressing localized type ever develops secondarily to an acute fulminating sinusitis. In any event we agree with Furstenberg and Mosher that the differentiation between a localized and a spreading, diffuse osteomyelitis is of no practical value to the surgeon as it is invariably a diagnosis in retrospect. The diagnostician does not exist who has the prophetic vision to foresee whether the process, which he is called on to eradicate in the acute stage, will remain localized or will spread. All osteomyelitis of the cranial vault should be removed completely as soon as the diagnosis is made.

(fig. 12). A blunt needle is then inserted through the cerebrum into the abscess and as much pus as possible is allowed to escape. The needle is withdrawn and the wound closed, bringing the end of the gauze out through the incision. Two days later the gauze is all withdrawn and approximately a week later the wound is reopened. In the interval the abscess may be aspirated, if necessary. When the wound is reopened the cerebral tissue overlying the abscess is removed by means of suction or with an electric cautery, and the abscess is incised and drained with large (diameter 1 cm.) firm rubber tubes.

There is only one point in the treatment of these abscesses which merits further discussion. Whenever possible the abscess should be approached through

uninfected tissue. All too frequently rhinologists and otologists operating in an infected field break the most invincible barrier to infection that the human body has—the dura mater. If the meningeal spaces have been obliterated this is, of course, without danger; but all too frequently such is not the case. Incision of the dura mater in an infected field is based on an erroneous assumption—that brain abscesses are produced by direct invasion of the brain through the dura mater. In fact, as we have earlier pointed out, the infection usually enters the brain through the venous system. Incision of the protecting dura mater in an infected field in the absence of a brain abscess exposes the leptomeninges directly to the infectious organisms and invites the development of meningitis. Even when an abscess is present, elevating the intracranial tension and compressing the meningeal spaces, the danger is by no means abolished and it would appear that this unwise procedure may account, in part at least, for the far too high mortality from this condition.

REGENERATION

Although regeneration of bony defects of the skull has long been known to occur, there is little available literature dealing with this subject. Furstenberg³ is one of the few to present any considerable number of cases and even he, unfortunately, gave few details. He studied eight cases in which bone had been removed from the cranium because of osteomyelitis. "In each of the eight patients now living and well, there is perfect obliteration of the cranial defect through the medium of regenerated bone." Most other authors, like Mollison,³¹ report a single instance and that briefly. The entire problem is badly in need of a thoroughgoing investigation with a large number of cases.

It is, however, our impression, along with that of many other neurosurgeons, that the defects secondary to the removal of osteomyelitic foci usually are repaired by bony regeneration, and that defects made by removing infected bone show a much greater tendency toward regeneration than bone removed with sterile technic, as in cases of brain tumor.

CONCLUSIONS

Three cases of cranial, intracranial and combined infection secondary to acute infection of the frontal sinus which followed swimming and one case in which such infection followed trauma to a styne were chosen as a basis for discussion. From these cases and a review of the literature it is concluded that:

1. The infection usually spreads to the frontal bone and invades the brain by way of the venous system.

2. Prevention of the fulminating frontal sinusitis, osteomyelitis and brain abscess, which so often follow swimming, can in a measure be attained by instruction regarding proper breathing and the use of protective devices. However, in the main prophylactic measures must be directed toward prevention of the spread of infection from the sinus. It appears that this can be best obtained by prompt external surgical drainage in the acute fulminating cases.

3. Osteomyelitis of the skull should be treated by excision of all of the infected bone as soon as the diagnosis is made.

31. Mollison, W. M.: Case Showing Re-Formation of Frontal Bone Removed Eight Years Ago for Acute Osteomyelitis. *Proc. Roy. Soc. Med. (Sect. Laryngol.)* 19 (pt. 3): 29 (Feb. 5) 1926.

4. Brain abscess should be drained through an uninfected area of the skull, if possible, with due attention to prevention of infection of the meninges.

5. Defects made by removing infected bone from the skull are probably usually repaired by the spontaneous regeneration of bone.

ANESTHESIA AND LIVER INJURY

WITH SPECIAL REFERENCE TO PLASMA
PROTHROMBIN LEVELS

AND

H. P. SMITH, M.D.

IOWA CITY

It is now a well established fact that patients with biliary fistulas or with chronic biliary tract obstruction do not absorb adequate amounts of vitamin K from the ordinary diet. Without absorption of this vitamin, prothrombin cannot be produced in the body and a marked tendency to bleed develops.

In many of these cases in which there are depleted reserves the prothrombin level is only slightly reduced prior to operation, but commonly it falls markedly after operation. This dangerous postoperative fall may be due to either of two factors: (1) excessive loss of prothrombin through hemorrhage at operation and through the postoperative formation of fibrin exudate in the margins of the wound and (2) interference with the manufacture of prothrombin by the liver. Such interference might result from decreased consumption of food or from injury to the liver. Such injury might be brought about by mechanical trauma at the time of operation or by absorption of toxic by-products from the operative site. Finally it might be produced by direct poisoning of the liver by the anesthetic agent employed.

Most workers¹ lean to the view that the anesthetic agent does produce sufficient liver injury to account for this postoperative fall in the prothrombin level.^{1a} This view appears, however, to be mainly conjecture, for in published data all the complicating factors mentioned were constantly present. We here present our own observations, which, except in the case of chloro-

1a. Warren and Rhoads, however, found that ether anesthesia in dogs failed to produce a prothrombin deficiency (Warren, Richard, and Rhoads, J. E.: The Hepatic Origin of the Plasma-Prothrombin Observations After Total Hepatectomy in the Dog. *Am. J. M. Sc.* 108: 193-197 [Aug.] 1939).

form, tend to minimize the role of anesthetics in affecting the prothrombin level. The two stage titration technic of Warner, Brinkhous and Smith² was used to determine the plasma prothrombin level.

THE EFFECT OF CHLOROFORM ANESTHESIA

That chloroform anesthesia produces injury to the liver of animals has been known for many years. More recently it has been shown by Smith, Warner and

TABLE 1.—*Chloroform Anesthesia: Plasma Prothrombin Levels*

Patient	Age	Operation	Duration of Anesthesia, Hours	Concentration of Anesthetic in Blood, Before Operation, Mg. per 100 Cc.*	Plasma Prothrombin Level, per Cent of Normal, Days After Operation						
					1	2	3	4	5	6

6	..	Repair of cleft palate	1½	15	82	66	69	59	67	80	83.5
Average					96	78	79	79	88	84	93

* Analytic method for chloroform in blood: Two cc. of blood was discharged into 20 cc. of a 5 per cent solution of tartaric acid in 50 per cent alcohol and 10 cc. of distillate collected. One cc. of the distillate was diluted to 10 cc. with water, and 2 cc. of this was heated on the water bath for three minutes with 4 cc. of 20 per cent sodium hydroxide and 3.5 cc. of pyridine (Cole, W. H.: The Pyridine Test as a Quantitative Method for the Estimation of Minute Amounts of Chloroform, J. Biol. Chem. 71: 173 [Dec.] 1926) with shaking. The sodium hydroxide layer was removed, the pyridine layer shaken with 12 per cent anhydrous sodium sulfate solution and removed and filtered. Trichloroacetic acid solution was used as a standard for the colorimetric comparison.

Brinkhous³ that owing to such injury there is a profound fall in the plasma prothrombin level.

That chloroform is injurious to the human liver has been accepted on clinical and autopsy evidence. The observations given in table 1 show that the prothrombin level also is influenced and falls markedly even though the anesthesia is not unduly prolonged. None of the patients listed showed evidence of vitamin deficiency or of preexisting disease of the liver or biliary tract, and in no case was there any manipulation about the liver at the time of operation. Only one of the patients had an intraperitoneal operation; the others had repair of a hernia or a harelip. The anesthesia varied in length from an hour to an hour and a half. Most of the patients were maintained in from light to moderate anesthesia (first or second plane, third stage). In case 5 the anesthesia was maintained at a lower level (third plane, third stage) for brief periods. The chloroform levels in the blood were determined in these cases and were found to be from 15 to 18 mg. per hundred cubic centimeters of blood.

Prior to operation the prothrombin levels were within normal range in all cases, though in case 6 it was only 82 per cent of the normal control level. Following operation there was a fall in every case with a variation of from 11 to 40 per cent and an average fall of 18 per cent. In some cases the lowest level was reached within twenty-four hours; in others it was not reached until from forty-eight to seventy-two hours had elapsed.

3. Smith, H. P.; Warner, E. D., and Brinkhous, K. M.: Prothrombin Deficiency and the Bleeding Tendency in Liver Injury (Chloroform Intoxication), J. Exper. Med. 65: 801-811 (Dec.) 1937.

In a number of cases the plasma was slightly icteric at this time and in cases 5 and 6 the icterus was quite marked.

Recovery from the injurious effects of chloroform is usually evident on the third or fourth postoperative day and is typically complete within a week. Case 6 is the only one in which recovery was definitely delayed.

In five of the cases the chloroform was administered in a closed system by the absorption technic, the inhaled atmosphere containing at least 50 per cent of oxygen. In case 6, however, anesthesia was induced by the open drop technic and was then maintained by pharyngeal insufflation. A certain amount of obstruction and asphyxia was present. In this case the prothrombin fell to the low level of 56 per cent and there was oozing of blood from the operative site at this time.

Ravdin and his co-workers⁴ have presented evidence to indicate that in dogs asphyxia aggravates the harmful effect of chloroform on the liver. When they administered chloroform in air, some asphyxia was present and liver necrosis was more evident than when the chloroform was administered in an atmosphere rich in oxygen. Under normal working conditions the use of oxygen is undoubtedly a desirable precaution, but we have found in experiments on dogs that by careful elimination of respiratory obstruction and depression there is no need for enriching the atmosphere with oxygen. To prevent obstruction we used a mask covered only by a thin layer of gauze. As a further precaution a catheter was placed through the larynx into the trachea. The accompanying chart shows results in a representative dog which received chloroform for an hour and a half along with a gaseous mixture rich in oxygen. A companion dog received chloroform for the same period by the open drop technic, including the necessary precautions to prevent asphyxia. The plasma prothrombin fell to approximately the same level and at approximately the same rate in the two dogs. The recovery periods were likewise similar. It is evident that oxygen in excess is beneficial only as far as it is needed to correct defective ventilation. Oxygen in excess of this does not minimize the injury to the liver.

Similarity in depression of plasma prothrombin levels in dogs given chloroform anesthesia by the open drop and absorption techniques when care is taken with both techniques to eliminate asphyxia.

Incidentally the curves of the chart illustrate the fact that the fall in plasma prothrombin is much greater in dogs than in man under equal conditions of anesthesia.

4. Goldschmidt, Samuel; Ravdin, I. S., and Lucké, Balduin: Anesthesia and Liver Damage: 1. Protective Action of Oxygen Against the Necrotizing Effect of Certain Anesthetics on the Liver, J. Pharmacol. & Exper. Therap. 59: 1-14 (Jan.) 1937.

THE EFFECT OF ETHER AND CYCLOPROPANE

There has been much interest in the possibility that ether, cyclopropane and other common anesthetic agents may likewise cause liver injury sufficient to produce the postoperative fall in prothrombin which is so commonly observed in the jaundiced bleeder. To study this problem we observed prothrombin levels in a number of cases in which operations were performed for

* Analytic method for ether in blood: One cc. of oxalated blood was distilled from 20 cc. of saturated picric acid solution into a cooled receiving flask containing standard dichromate solution (2.1288 mg. per liter; 10 cc. = 4.02 mg. of ether). Concentrated sulfuric acid (20 cc.) was added through a reflux tube. The excess dichromate when cool was titrated with a mixture of sulfuric acid, methyl red and ferrous sulfate according to Harger (A Simple Micromethod for the Determination of Alcohol in Biologic Material, J. Lab. & Clin. Med. 20: 746 [April] 1935).

† Analytic method for cyclopropane in blood: Five cc. of blood plus 5 cc. of water were aerated through an iodine pentoxide train, the iodine released being caught in potassium iodide solution and determined iodometrically (Robbins, B. H.: Cyclopropane: A Method for Quantitating Cyclopropane in Air and Blood: Concentrations of Cyclopropane in the Air and Blood Necessary for Anesthesia, Loss of Reflexes and Respiratory Arrest, Anesth. & Analg. 16: 93 [March-April] 1937).

various conditions. In all cases the anesthesia was administered by the absorption technic when an atmosphere containing at least 50 per cent of oxygen was used.

In table 2 patients 1 to 6 had conditions independent of disease of the liver or gallbladder, whereas patients 7 to 10 had gallbladder disease without jaundice or biliary fistula. These patients were given ether. There were a few irregularities in results, owing in part at least to unavoidable errors in the determination of the plasma prothrombin level. However, there was no consistent change in any of the cases and the average values show, if anything, a slight rise in prothrombin following operation. In all cases the anesthesia was of at least an hour's duration and in a number it was from two to four hours. In many cases there was a major operative wound and significant tissue trauma. In cases 11 to 14 cyclopropane anesthesia was used and was likewise without effect on the plasma prothrombin levels.

COMMENT

The marked fall in prothrombin which occurs postoperatively in patients with obstructive jaundice and biliary fistulas cannot be explained purely on the basis of these two anesthetic agents. It is evident that other factors play an important role. We have reason to believe that even when the individual suffers from Vitamin K deficiency the anesthetic alone has little or no effect on the plasma prothrombin level. In several dogs with obstructive jaundice or biliary fistula, in which the plasma prothrombin level fell over a period of weeks to from 30 to 70 per cent of normal, simple ether or cyclopropane anesthesia did not produce any further fall in the level.

The factor of trauma in causing the postoperative fall in prothrombin has been stressed by Lord.⁵ He found that in healthy dogs massage of the liver for twenty-five minutes produced a fall of from 20 to 30 per cent in the plasma prothrombin level. We have confirmed these results. In view of the lack of depression of the prothrombin level by ether and cyclopropane, it would seem that other factors such as mechanical trauma are more significant in the production of the fall in prothrombin observed in clinical practice.

SUMMARY

Chloroform anesthesia produces a fall in the plasma prothrombin level in man; this observation extends work done previously on animals. Neither ether nor cyclopropane anesthesia produces any such effect in the uncomplicated cases which we have reported. The fall in the plasma prothrombin level which occurs after operation in patients with obstructive jaundice or biliary fistulas is evidently due essentially to factors other than the anesthetic agent itself.

ABSTRACT OF DISCUSSION

DR. HUBERTA M. LIVINGSTONE, Chicago: During the past year Dr. J. Garrott Allen of the University of Chicago and I have studied the effect of ether, ethylene-oxygen, avertin with amylene hydrate, vinethene, and spinal and local anesthesia on the prothrombin concentration in the human being subjected to surgical procedures. These studies were carried out on twenty-two patients who had initial prothrombin deficiency and on sixty-eight patients in whom no prothrombin deficiency was present before operation. We conclude that ordinary anesthetics, blood loss and surgical trauma have little to do with changes in the prothrombin. Of the patients suffering from prothrombin deficiency brought on by either obstructive jaundice or biliary fistula, there was a fall in prothrombin concentration during the postoperative period even though the initial prothrombin deficiency had been corrected by vitamin K or one of its substitutes. This postoperative hypoprothrombinemia was regularly found between the first and seventh postoperative days, and it occurred even when local or spinal anesthetic agents were used. We have observed, however, that a close correlation existed between duration and intensity of preoperative vitamin K therapy and the rapidity with which the postoperative prothrombin deficiency appeared. Since none of the patients of either group received food by mouth before the fourth postoperative day, it is apparent that the prothrombin level must therefore have been maintained by the reserves of potential prothrombin present in the body at the time of the surgical operation. Thus it would seem that the length of time prothrombin concentration could be maintained at a normal level during the postoperative period would depend on the quantity of this reserve present at the time of operation. The sixty-eight patients studied in group 2 were selected because extensive surgical procedures were contemplated. Blood loss determinations carried out on ten of these patients showed a loss ranging from 420 to 1,150 cc., while the anesthetic periods ranged from one hour and twenty minutes to four hours and

5. Lord, J. W., Jr.: Effect of Trauma to the Liver on the Plasma Prothrombin, Surgery 6: 896 (Dec.) 1939.

forty-five minutes. Of this entire group only one case showed any fall in prothrombin during the postoperative period. In this patient icterus developed on the second postoperative day associated with oliguria and hyperpyrexia, and she died on the fourth postoperative day, apparently of acute hepatic failure, although no autopsy was obtained. The results of our studies would seem to indicate that the most significant cause of the postoperative hypoprothrombinemia in the jaundiced and biliary fistula patients is not anesthesia or operative procedure but rather the failure to establish an adequate prothrombin reserve before operation.

DR. MILTON C. PETERSON, New York: The present widespread enthusiasm and interest with regard to prothrombin levels and vitamin K in the field of surgery makes it essential that the anesthetist be concerned with the prothrombin level as far as its relationship to anesthesia is concerned. In the discussion of this paper the project presented is much larger than might ordinarily be thought of at first observation, since the prothrombin level is dependent on vitamin K, its absorption and the function of the liver, which, as has been pointed out, may be impaired from a number of factors. Still another variable is presented, as the authors have stated, the unavoidable errors in the determination of plasma prothrombin level. In this regard I should like to ask Within what limits must a change occur to be significant with their methods? Also What percentage variation do they consider to be within the normal limits of determination? The apparent discrepancies between the observations of the present authors and those of Dr. Ravdin and his co-workers with regard to liver damage, with and without oxygen enriched mixtures, is at present without significance, as observations were made on histologic and pathologic studies of the liver itself, which may or may not parallel the plasma prothrombin level. This correlation has not been definitely established. Dr. Bourne's studies of liver function by means of dye retention would indicate impairment of liver function for a somewhat longer period of time than is suggested by alterations in the prothrombin level. It was stated that ether and chloroform did not cause a depression in prothrombin level. From the data presented, this would appear true of ether. On the other hand, one of four cases with cyclopropane demonstrated a fall equal to the average fall of the ten chloroform cases presented, although the other three cases demonstrated an insignificant fall or a rise. Because of the complicated variables in this study, conclusions must be guarded until a sufficiently large series is presented to equalize the variance.

DR. MAX H. WEINBERG, Pittsburgh: I should like to ask a question as to the method used in making these tests.

DR. STUART C. CULLEN, Iowa City: In answer to Dr. Peterson, who questions the extent of the limits of variability in prothrombin determinations, it can be said that the limits vary within 20 per cent. That is, a variation in normal individuals from 100 to 80 per cent would be considered within the limits of normal. Dr. Peterson also questions the advisability of using the plasma prothrombin determinations as a test of liver function. Comparative studies with other liver function tests have been done and indicate that function is equally reflected. It is evident that the number of cases followed in which cyclopropane was used is minimal and deserves further investigation, but it is hardly probable that any such conditions as occurred with chloroform will develop. Even though the average fall with chloroform was only 18 per cent, there was a wide variation from 11 to 40 per cent. Dr. Weinberg asked which method for the determination of plasma prothrombin was used. We used the two stage titration method of Warner, Brinkhous and Smith.

Millions of Casts.—The occurrence of casts in the urine of apparently healthy individuals has been shown by Addis. In subjects who were required to abstain from fluid during the day, the night urine (twelve hour period) contained on an average an estimated number of 1,040 casts, with individual values varying from 0 to 4,270. These numbers are insignificant in comparison to the tens and hundreds of thousands, and even millions, of casts excreted in a like period by nephritic patients. —Bodansky, Meyer, and Bodansky, Oscar: *Biochemistry of Disease*, New York, Macmillan Company, 1940.

THE TREATMENT OF CHRONIC DEAFNESS AND TINNITUS AURIUM WITH PROSTIGMINE

KARL MUSSER HOUSER, M.D.

EDWARD H. CAMPBELL, M.D.

AND

HARRY SCHLUEDERBERG, M.D.

PHILADELPHIA

In 1939 Davis and Rommel¹ reported a series of twenty-four cases of deafness and tinnitus aurium treated with prostigmine methylsulfate hypodermically, along with oral administration of prostigmine bromide. They concluded that patients with acute symptoms usually had restoration of hearing following five or fewer injections, that chronic cases showed encouraging results but responded less rapidly, and that tinnitus aurium was relieved or reduced.

A critical study of this work revealed that accurate hearing tests have not been used in the estimation of hearing loss both before and after treatment. On this account a letter was sent to the company manufacturing the drug stating this fact and asking if the company would cooperate in a comprehensive and well controlled clinical study of the effect of the product on hearing and tinnitus in several Philadelphia clinics. Full cooperation was obtained, and an adequate supply of materials was furnished for the test.

A series of fifty-six cases were studied and treated in the University of Pennsylvania, the Pennsylvania and the Episcopal Hospital clinics. No acute or subacute cases of tympanic and tubal inflammation were included, because such cases properly treated almost always recover without the use of prostigmine.

All cases were first studied with tuning forks and audiometers in the attempt to secure an accurate determination of hearing loss and the type of deafness present. In the table the average decibel and percentage loss is given for only 512, 1,024 and 2,048 frequencies. In testing, however, decibel losses for frequencies from 128 to 8,192 inclusive were obtained. The duration of deafness in the group studied had existed from one to eighteen years. Tinnitus aurium in some degree was present in all but six cases. The age limit was from 13 to 70 years. Most cases were treated and kept under observation for three months, none of the series being treated for less than two months. During the treatment period 1 cc. of prostigmine methylsulfate, 1:2,000 dilution, was given hypodermically every third day. In addition 15 mg. of prostigmine bromide was given after meals during the first six weeks of treatment. Audiograms were taken every two or three weeks while treatment was in progress. Local treatment if indicated, such as inflation and massage, or attention to nose, throat or sinuses, was not interrupted during the treatment period.

It is well recognized by otologists that audiograms taken on separate occasions will not always give identical readings in either the normal or the hard of hearing patient. Usually one allows for a +7 or -7 decibel variation. This fact should be understood lest one draw inaccurate conclusions from a decibel change of 15 or less. In our series seven patients, 12.5 per

1. Davis, T. Carroll, and Rommel, John C.: Treatment of Deafness and Contiguous Nervous Disorders with Prostigmine. *Arch. Otol.* 29: 751-758 (May) 1939.

cent, showed improvement in the right ear of 10 decibels or more. On the left side, 7.1 per cent were improved in this degree. Only two patients improved more than 15 decibels. Cases showing a + 10 decibel or more gain can be identified in the table by referring to cases 4, 7, 9, 16, 24, 29 and 30. Of these patients only three, 16, 19 and 24, had enough improvement to be

their tinnitus. No untoward symptoms, except occasional slight nausea and minor vertigo, were reported by any patient.

CONCLUSIONS

1. In a series of fifty-six carefully tested and controlled cases of chronic deafness, prostigmine treatment failed to exert a definite beneficial effect.

appreciable to the patient. One of these, patient 19, was syphilitic, and no improvement occurred until anti-syphilitic therapy was given. The final result then was two patients, 3.5 per cent, who felt that any practical improvement in hearing had occurred.

Seven of the treated patients felt that they experienced some relief of tinnitus, three were doubtful and forty-six were definitely not improved. No patients lost

2. It is doubtful that any real effect is produced on tinnitus aurium. Seven patients felt that some improvement had taken place. None lost their tinnitus completely.

3. Our studies lead us to believe that the treatment of deafness and tinnitus aurium with prostigmine is of but little if any value.

2010 Spruce Street.

FETAL AND NEONATAL DEATHS

A STATISTICAL ANALYSIS OF 2,000 AUTOPSIES

EDITH L. POTTER, M.D.

CHICAGO

In the Department of Obstetrics and Gynecology of the University of Chicago from Oct. 1, 1934, until April 1, 1940, we have had the opportunity of examining at autopsy more than 2,500 fetuses and infants of varying gestational age and extra-uterine age up to 1 year. This has in part been made possible by the cooperation of Dr. Herman Bundesen, president of the Chicago Board of Health.

The present report is based on 2,000 autopsies which comprise the entire group with the exclusion of the fetuses classed as abortions,¹ the infants over 1 month of age and those in which adequate maternal and infant histories were unavailable.

TABLE 1.—*Gestational Age in Relation to Time of Death*

	Previsible	Premature	Term	Total
Antepartum death	160 (8.0%)	265 (13.25%)	227 (11.35%)	652 (32.6%)
Intrapartum death	95 (4.75%)	139 (6.95%)	319 (15.95%)	553 (27.65%)
Neonatal death....	155 (7.75%)	348 (15.4%)	292 (14.60%)	795 (39.75%)
Total.....	410 (20.5%)	753 (37.6%)	838 (41.9%)	2000 (100%)

Six hundred and eight of the fetuses and infants were born and died at the Chicago Lying-in Hospital, 895 were sent to us for autopsy, and 497 were examined at autopsy elsewhere by Dr. Aaron Gunther for the Chicago Board of Health and tissues sent to us for microscopic examination. In each case a complete autopsy including examination of the head was performed and tissues were subjected to microscopic study. In all macerated fetuses and in others in which there was any suspicion of syphilis, Levaditi stains for spirochetes were included. Bacterial cultures and other procedures were used when indicated. The placentas were available for study in almost half of the cases. I made all microscopic examination of the tissues. The method of autopsy and the criteria on which the diagnoses were based have been reported in detail in other publications and will not be reviewed here.²

In such a series the sequence of events which has led to the death of any infant cannot be unfolded in detail, and often from the multiplicity of conditions which have played a part in the disastrous outcome only a single one, which to the investigator seems most important, can be recorded. The five factors which must be considered in each case are the time of death in relation to birth, gestational age at birth, method of delivery, complications of pregnancy and labor, and the pathologic lesions present in the body of the fetus or infant. In order to be as lucid as possible, I will discuss these various conditions individually.

From the Department of Obstetrics and Gynecology, the University of Chicago and the Chicago Lying-in Hospital.

Read before the joint meeting of the Section on Obstetrics and Gynecology and the Section on Pediatrics at the Ninety-First Annual Session of the American Medical Association, New York, June 14, 1940.

1. If the fetus fulfilled two of the three following criteria, it was classed as an abortion: length less than 35 cm., weight less than 400 Gm., gestational age less than twenty-two weeks. The arbitrary division is used since the Illinois law requires the reporting of all stillbirths in which the fetus is advanced to the fifth month of gestation.

2. Potter, Edith L.: Postmortem Examination of Stillborn and Newly Born Infants, Arch. Path. 25: 607 (May) 1938. Potter, Edith L., and Adair, F. L.: Fetal and Neonatal Deaths: An Analysis of 773 Such Deaths Occurring with 17,738 Deliveries at the Chicago Lying-in-Hospital, J. A. M. A. 112: 1549 (April 22) 1939; Fetal and Neonatal Deaths, Chicago, University of Chicago Press, 1940.

AGE AT DEATH

Of the entire series 1,205 (60 per cent) fetuses were stillborn and 795 (40 per cent) were alive at birth. Six hundred and fifty-two (32 per cent) of the fetal deaths occurred prior to the onset of labor and 553 (28 per cent) took place during labor or delivery. Of the infants that were born alive 193 (24 per cent) lived less than one hour, 360 (45 per cent) more than one and less than twenty-four hours, and ninety-three (12 per cent) from twenty-four to forty-eight hours. One hundred and thirteen (14 per cent) died between the end of the second day and the end of the second week, and thirty-six (4.5 per cent) succumbed during the third and fourth week. One hundred and sixty-five infants who died between the end of the first month and the end of the first year were also examined during the course of this study but are not included in this discussion. It is interesting to note that the number of infants dying during the first forty-eight hours of life is identical with the number of antepartum deaths.

Seventy per cent of the 795 deaths occurred under forty-eight hours. This strikingly illustrates the fact, stressed by many investigators, that the first two days are the most crucial in the infant's entire existence. The majority of deaths during this time are the result of harmful conditions affecting the fetus during labor or delivery, and, if neonatal mortality is to be appreciably lowered, effort must be directed toward removing injurious conditions operating before the infant is born.

In the entire series 410 (20.5 per cent) fetuses and infants were previsible,³ 753 (37.6 per cent) were viable premature⁴ and 838 (41.9 per cent) were at term (table 1). The stage to which pregnancy had advanced when death or delivery occurred is much the same in the antepartum, intrapartum and neonatal groups except

TABLE 2.—*Anatomic Manifestations in Relation to Time of Birth*

that during the intrapartum period the incidence among previsible and premature infants is disproportionately low, suggesting that the factor of immaturity may be more of a hazard in establishing an extra-uterine existence than it is during the passage through the birth canal.

3. Two of the three following criteria: weight from 400 to 999 Gm., length from 22.1 to 35 cm., menstrual age 22 through 28 weeks.

4. Two of the three following criteria: weight from 1,000 to 2,499 Gm., length from 35.1 to 47 cm., menstrual age 29 through 47 weeks. Infants and fetuses falling in this group are hereafter referred to only as "premature."

ANATOMIC ABNORMALITIES FOUND AT AUTOPSY
(TABLE 2)

No abnormalities⁵ could be demonstrated in the bodies of 43.5 per cent (870) of the 2,000 fetuses and infants. This ranged from 80 per cent in the previable fetuses dying before the onset of labor to only 13 per cent in the mature infants dying after birth. In general, irrespective of the time of death, 70 per cent of the previable group failed to show pathologic changes, and even in those in whom abnormal conditions were found the lesions can hardly be considered the cause of death, since the infants would have died immediately after birth even in their absence. The actual causes of death must be sought in the conditions which incited labor prematurely. Also about 70 per cent of all fetuses who died before the onset of labor failed to show demonstrable changes other than maceration. In the term infants and fetuses who died during labor or after birth, pathologic lesions were absent in only about 15 per cent.

In the total autopsies, evidence of asphyxia⁶ was the pathologic state most frequently found and was present in 19.4 per cent (378). It was more common when death occurred during the intrapartum period (40 per cent in premature and term fetuses) than at

ous study of the fetal and infant deaths occurring at the Chicago Lying-in Hospital we have shown that of every 1,000 infants delivered there were about ten mature and ten premature who died. Two of the mature and one of the premature showed traumatic hemorrhages.

The total injuries in the present series consisted of 244 instances of hemorrhage within the cranial cavity, twenty-eight lacerations of abdominal organs and two fractures of the spinal column. In ninety intracranial hemorrhages the exact locus was unstated, in 129 it was associated with rupture of the vein of Galen or the dural sinuses, in twenty-four it was intraventricular (this was practically the only variety found in previable fetuses) and in eleven it was diffuse over the cerebral hemispheres. In twenty-four of the visceral injuries the organ involved was the liver; in the remaining four the hemorrhage was in the adrenals. In two cases the spinal cord was completely severed.

Malformations incompatible with life were found in 10.3 per cent (209) of the entire group. They were much more commonly a cause of neonatal death (14.4 per cent) than of stillbirth (antepartum death 6.7 per cent, intrapartum death 9.4 per cent) and were most often found in those infants who were born alive at

any other time and was found in only 6 per cent of the infants born alive. The majority (80 per cent) of deaths in live born infants from this cause occurred in the group living less than twenty-four hours and in many of these respiration was never established. The complications which were present in association with this condition were much the same in the fetuses who died after birth and those who died during labor. They consisted largely of maternal hemorrhage from placenta praevia or premature placental detachment or from entanglements, prolapse or other abnormalities of the umbilical cord.

Traumatic hemorrhage was found in 14.3 per cent (274) of the entire group and was second in frequency to asphyxia. Its incidence in term infants dying either during labor or after birth was almost twice as great as in the premature and either two or three times greater than in the previable fetuses dying in the same periods. This indicates that of 100 mature infants and 100 premature infants who die during labor the likelihood of the mature infant succumbing as a result of mechanical injury and hemorrhage is twice as great as of the premature succumbing from the same cause. It must be kept in mind, however, that in general the total mortality rate for premature infants is from fifteen to twenty times as great as for those at term. In a previ-

term (22.0 per cent). Almost half (44.7 per cent) of the malformations consisted of hydrocephalus or anencephalus and the remainder were divided between cardiac 10.4 per cent, skeletal 7.6 per cent, gastrointestinal 4.2 per cent, miscellaneous and multiple anomalies 5.2 per cent. In addition to these major malformations there were thirty-eight minor anomalies such as clubfoot, harelip, extra digits and others in which the abnormality was not considered a cause of death.

Syphilis was definitely demonstrated in the bodies of only twenty-six (1.2 per cent) fetuses and infants. In an additional forty-seven there was a history of maternal syphilis or the Wassermann reaction was positive sometime during pregnancy. Many of these syphilitic women had been under treatment for varying lengths of time and in many of the offspring other definite abnormalities were present, so that although in some of these instances syphilis may have been a contributing factor, it was not the principal cause of death.

Infections other than syphilis were present in 158 (7.9 per cent) instances as the major cause of death. Almost all of these were pneumonia and occurred most commonly among the infants who died after birth (124, or 15.6 per cent), although evidence of intra-uterine pneumonia was present in 2.5 per cent (ten) of the fetuses dying before the onset of labor and in 4.4 per cent (twenty-four) of those dying during labor. Pneumonia occurring in fetuses who die prior to the onset

5. Maceration was not considered a pathologic lesion.
6. In this paper "asphyxia" is used to mean a condition in the fetus resulting from oxygen deprivation caused by obstruction to the umbilical circulation.

of or during labor and in infants who succumb within a few hours or days after delivery usually has a common etiologic background. Bacteria are admitted entrance to the amniotic fluid through early rupture of membranes, prolonged labor or some other complication. Aspiration of amniotic fluid introduces organisms into the lungs of the fetuses and an inflammatory reaction ensues. The possibility of pneumonia is a definite hazard to the fetus during a long and complicated labor, particularly when the membranes have ruptured early. In the majority of deaths from pneumonia such conditions were found.

The incidence of pneumonia as a cause of death increases with each day of extra-uterine life. It accounts for 6 per cent of the deaths on the first day, 18 per cent on the second, 32 per cent from the end of the second day to the end of the second week and 50 per cent during the third and fourth weeks. Among the 165 infants not included in this study who died between the end of the first month and the end of the first year, 63 per cent died of infections, largely pneumonia

All fetuses dying in the antepartum period or who were previable, malformed or suffering from syphilis and erythroblastosis have been eliminated.

(table 3). This does not include those cases in which the pneumonia was secondary to a communicable or other known disease.

In addition to the 7.9 per cent of fetuses and infants in which pneumonia was considered the primary cause of death, it was found in 3.7 per cent (seventy-four) as a complicating factor in combination with some other fundamental lesion. Intracranial hemorrhage (forty-four cases) was the condition with which it was most frequently associated.

METHOD OF DELIVERY

The pole of the fetus which presents in the maternal pelvis and the methods by which delivery is accomplished either as a result of natural forces or because of artificial termination necessitated by various complications bear an important relationship to the pathologic states found in the offspring. Deaths in which manner of delivery could have played no part include those which occurred before the onset of labor and those in which the fetus was previable, fatally malformed or suffering from erythroblastosis or extensive syphilis. If these, plus the fetuses on whom destructive operations were performed, are eliminated 787 cases remain (table 4). In caudal presentations, and in all operative terminations of labor except cesarean section, hemorrhage due to trauma was the most frequent cause of

death and was found more than twice as often as in natural cephalic delivery. In caudal deliveries the incidence was more than twice as great as in natural cephalic deliveries. This difference is not due to the fact that the number of the premature infants delivered by

TABLE 5.—*Maternal Complications Present in 1,033 Women in Association with 2,000 Fetal and Neonatal Deaths*

breech is proportionately greater than the natural cephalic deliveries. If mature infants alone are considered, the proportion of infants dying in the intrapartum and neonatal periods who show intracranial injury is 43.7 per cent in the caudal deliveries and 19.2 per cent in cephalic deliveries. Caudal presentation presents a distinctly greater hazard of birth trauma to the fetus than does a cephalic presentation. The incidence of infections in the fetuses and infants delivered by breech is only a little more than one fourth that found in those who are delivered naturally in a cephalic presentation. No explanation is known.

Complications of pregnancy or labor were present in 1,033 women (51.6 per cent, table 5). In 111, more than one condition was found. Toxemia occurred as the most common complication and was present in 12.6 per cent (253) of the mothers included in this study (these consisted of twenty-one cases of eclampsia, thirty cases in which hypertension alone was present, seven cases of hyperemesis gravidarum and 194 in which albuminuria, hypertension and edema were pres-

ent). This is almost twice the incidence of toxemia (7 per cent) found by Dieckmann in the total mothers delivered at the Chicago Lying-in Hospital. It was considered the probable cause of death in only 4.9 per cent, or only when no demonstrable cause could be found in the bodies of the fetuses or infants. I have hesi-

tated except on rare occasions to say that toxemia was the specific cause of death, since it produces no definite pathologic changes and the infants of toxemic mothers may die of the same conditions which affect those born of nontoxemic mothers. It is perhaps wiser in such cases to say that the infants show no abnormalities but that there was an associated maternal toxemia.

Abruptio placentae was second in frequency with an incidence of 7.6 per cent (150). The placental and cord disturbances, which so frequently lead to fatal asphyxia in the fetus, when added together were found in 22.3 per cent of the cases and in the final analysis were considered the probable immediate cause of death in 14.4 per cent. Abnormalities of labor due to uterine inertia, contracted pelvis and so on occurred in 7.5 per cent and were considered in 5.2 per cent to have caused death by the production of asphyxia or intracranial injury.

Maternal complications accounted for 30 per cent, or almost one third of the entire group of deaths; in 48 per cent no known complications of any kind were present; in the remaining 22 per cent some condition found at autopsy was considered of more significance than the maternal complications.

for 20.7 per cent (416) of all deaths. Asphyxia 16.1 per cent, birth trauma 12.7 per cent, and malformations 10.4 per cent make up the next three leading causes. Pneumonia 6.5 per cent, infants otherwise normal but born of mothers with toxemia 4.7 per cent, erythroblastosis 1.8 per cent, syphilis 1.2 per cent and miscellaneous 1.1 per cent compose the remainder. The higher incidence of pneumonia in this series than that found in the majority of reports is probably due to the fact that secretions of all lungs were examined microscopically. It is almost impossible in the newborn to make a gross diagnosis of this condition, and without microscopic examination these infants are usually considered to be suffering from atelectasis.

This clinicopathologic classification of fetal and infant deaths was used as a basis of an attempt to discover what role maternal age, parity, color and the sex of the infant might play in the fatal outcome.

MATERNAL AGE

The maternal age was stated in 1,881 cases (table 7). In comparison with the figures showing distribution of live births in relation to maternal age compiled by the Bureau of the Census, the present series shows

TABLE 7.—*Maternal Age in Relation to Cause of Death*

* Antepartum deaths before term.

† Includes antepartum deaths in succeeding order: 6, 25, 33, 37, 24, 12, 3.

Eleven maternal deaths occurred in this series during pregnancy or in the immediate postpartum period. Two women died undelivered, one from hemorrhage as a result of rupture of the uterus, the other of eclampsia. Of the other nine, four deaths were due to hemorrhage (two associated with placenta praevia and two with premature detachment) and five were from eclampsia.

FINAL ANALYSIS

When all the information that could be obtained was at hand, each case was reviewed and a final conclusion reached as to the most probable cause of death (table 6).

In approximately 25 per cent no known factors were present in the maternal history which might reasonably have been expected to contribute to the fatal outcome, and no abnormalities were found in the bodies of the fetuses. Three fourths (376) of these died before the onset of labor. This group of fetuses in nontoxemic women who die without apparent cause present one of the most baffling problems in the study of fetal deaths and one which is in need of further investigation. The other one fourth (104) of the unknown group were at term and died during labor or after birth. Thus, only 5.2 per cent of the series died during labor or after birth of entirely unknown causes.

Among those in whom a cause of death was postulated, prematurity without demonstrable pathologic lesions made up the greatest number and accounted

a lower incidence of deaths in the mothers under 30 and a higher incidence over 30 than would be expected if the deaths were distributed evenly at all ages in proportion to births. The mother over 30 has proportionately a greater chance of having a dead baby than the mother under 30.

Most of the causes of death show little variation in incidence in the various maternal age periods, but several interesting factors may be noted. Although the incidence of antepartum deaths before fetal maturity averages about the same at all ages, prematurity without demonstrable pathologic conditions as a cause of death during or after birth is proportionately much more common in younger than in older women. There is a steady decline from 30.8 per cent in women less than 20 years of age to 7.9 per cent in the age group over 40. It would appear that although a woman under 30 is in general less likely to have a dead baby than is one over 30, if death does occur the infant is more apt to die of prematurity and is less apt to show definite pathologic lesions than is that of the older woman. The lower incidence of deaths from prematurity among older women cannot be definitely explained. Although some data have been published which seem to indicate a slightly longer period of gestation in multiparous than in primiparous women, in the present study the incidence of prematurity among primiparous and multi-

arous women is the same, so that this does not seem to be the cause. It may be that the improved social conditions which often come with increase in age or better antepartum care resulting for increased desire for motherhood may play a part in preventing premature labor.

No known factors, term.....	79	11.7	160	13.3
Total.....	676	100.0	1,205	100.0

The incidence of maternal toxemia in the absence of demonstrable pathologic changes in the infants and fetuses shows a fairly steady increase from 0.5 per cent in the age group under 20 years to 11.9 per cent in the group over 40 years.

Erythroblastosis shows a gradual but steady increase from 0 per cent under 20 years of age to 4 per cent over 40 years.

The incidence of birth trauma, malformations, asphyxia and infections shows little variation in incidence in the various age groups except that asphyxia is somewhat more and malformations are somewhat less frequent than the average in the age period over 40 years.

PARITY

The number of previous pregnancies which the mother had undergone was stated in 1,881 of the 2,000 cases. Because of the inadequacy of specific informa-

tion concerning abortions, no attempt was made to differentiate parity and gravidity. There were 676 who had had no previous pregnancies, 1,205 who had had one or more. Of these 389 had had one, 241 had had two, 171 three, 112 four, 79 five and the remainder six or more previous pregnancies. There is no appreciable difference between the incidence of any condition as a cause of death in the primigravida and multigravida with the exception that erythroblastosis does not appear in the first group and accounts for 3.2 per cent (thirty-

eight cases) in the second group; and the incidence of birth trauma is almost twice as great in the primigravida as in multigravida.

COLOR

The color was stated in the total 2,000 fetuses and infants; 1,728 (86.4 per cent) were white. Of the remainder 267 (13.6 per cent) were Negroes, two were Chinese and three were Mexican. The most marked differences in incidence of the various conditions in the two groups is in syphilis, which is five times as frequent among the Negroes as among white persons and in malformations, which are twice as common in white persons as in Negroes. Prematurity and infections are slightly but not appreciably higher among Negroes, while asphyxia and birth trauma occur with slightly less frequency.

SEX

Sex was stated in 1,910 instances; 54.5 per cent (1,040) were male, 45.5 per cent (870) female. The sex ratio for total births is 1,000 females to 1,004 males. In this study the ratio is 1,000 females to 1,200 males. No marked variations in cause of death were found in the two groups. Malformations show the greatest

difference with an incidence of 8.4 per cent among males and 12.9 per cent among females, and birth trauma ranks next with an incidence of 14.4 per cent among males and 11.0 per cent among females. When the incidence of the various causes of death is calculated in individual groups in the antepartum, intrapartum and neonatal period, no further variations in relation to differences between the sexes are brought out.

SUMMARY

Fetuses dying before the onset of labor comprise almost one third of the total cases studied in this series. In approximately one half of these there were maternal conditions which may have caused death, and in at least one third there were neither maternal complications nor pathologic changes in the fetus. Toxemia and placental detachment were the most common two complications.

Deaths in the intrapartum period are usually due to some disturbance of the normal mechanism of labor and delivery. Intracranial hemorrhage is considerably more common in association with caudal and all artificial deliveries than in natural cephalic terminations of labor. The incidence of trauma among the premature group is less than that found in the mature group. Complications arising during pregnancy or labor are usually the reason for artificial terminations.

Deaths in the neonatal period are most frequently due to prematurity, secondly to birth trauma, thirdly to

malformations. Pneumonia is an extremely important condition and after the end of the first forty-eight hours is the leading cause of death.

CONCLUSIONS

It is extremely difficult to say in general which deaths are preventable and which are not. Those from malformations in our present state of knowledge are entirely nonpreventable, but all others theoretically are at least basically preventable. Although it is practically impossible to keep a previable infant alive, and this is a nonpreventable death after delivery has once occurred, modification of the status of the maternal organism before or during pregnancy might have permitted the pregnancy to go to term. If premature detachment of the placenta once occurs it is almost impossible to save the life of the fetus, but here again modification in the conduct of pregnancy and labor might have controlled the factors which eventually led to the separation. In competent hands the knowledge which we now possess is capable of reducing infant and fetal mortality rates to at least half of the current rates for the country as a whole. As our knowledge increases a nearer and nearer approach to the "irreducible minimum," which consists only of malformation, will be made and eventually perhaps even the cause of these will be discovered.

The fields in which the most reduction can at present be made are in those deaths due to trauma sustained during labor, to pneumonia, and in some parts of the country those due to syphilis.

The most common causes of death are as yet unsolved as to basic etiology and no known methods of prevention exists. The greatest saving of lives would be effected by the discovery of the cause of antepartum fetal death in nontoxic nonsyphilitic women, of the cause of premature onset of labor, and in the prevention of premature detachment of the placenta and placenta praevia.

Chicago Lying-In Hospital and Dispensary.

ABSTRACT OF DISCUSSION

DR. LUDWIG A. EMGE, San Francisco: Dr. Potter's talk is timely. Yesterday I pointed out in my chairman's address that the value of our efforts is greatly enhanced by cooperation. If physicians at large would be more cooperative in obtaining permission for autopsy the study of fetal and neonatal deaths would be greatly facilitated. Constituted authorities, particularly the health officers, are anxious for better information on infant deaths. Only if we cooperate to the fullest extent can this be achieved.

DR. EDITH L. POTTER, Chicago: I did not have time to show all that came out of this study. I have been glad of the opportunities afforded for autopsy study and I am grateful to the members of the Chicago Board of Health for their cooperation. If much is to be accomplished in the further reduction of neonatal deaths, it must be aided by individual investigation in individual hospitals. This series shows only general trends; it shows what is happening in our part of the country. If each individual hospital could examine its own infants and find out what is happening in that particular group, the obstetricians and the pediatricians would be stimulated. One frequently hears the statement that it is not worth while to "post" a baby because so little is usually found. In the material that I showed, only 5 per cent of the infants at term who were born alive failed to show some definite change at autopsy. It is just as important, however, to have negative observations as it is positive ones. It is just as important to know that an intracranial hemorrhage, a rupture of the liver or pneumonia is not present as it is to have those things definitely demonstrated.

DERMATITIS OF THE HANDS IN HOUSEWIVES

ROLE OF SOAPS IN ITS ETIOLOGY AND METHODS FOR ITS PREVENTION

JAMES W. JORDON, M.D.

FRANK A. DOLCE, M.D.

AND

EARL D. OSBORNE, M.D.

BUFFALO

Eczematous dermatitis of the hands in housewives is one of the commonest and most refractory conditions for which dermatologists are consulted. Although we recognize that a diversity of allergens may cause this type of dermatitis, it is our belief that the majority of cases are caused by hypersensitivity to ingredients of soaps and allied cleansers.

In 1936 we¹ did extensive patch test experiments both on normal individuals and on patients who had an eczematous type of dermatitis in an attempt to determine the allergenic properties of soaps. The results of that study convinced us of the importance of soaps, laundry preparations and allied household cleansers in the production of eczema.

In this study we discuss the pertinent chemistry of soaps and allied cleansers, report our observations on the clinical features of housewives' eczema due to these substances and evaluate patch tests as a diagnostic procedure in individual cases. Methods of prevention and control of this common condition will be discussed.

Soap, by definition, is a metallic salt of a higher fatty acid but, for practical purposes, because all others are insoluble, only the sodium, potassium or, rarely, ammonium salts are used for cleansing purposes. Soap manufacturers employ a large number of fats and oils both of animal and of vegetable origin in the manufacture of soap. Fats and oils are a mixture of the glycerides of the higher fatty acids. The type and amount of fatty acids present in a fat or oil depend on its origin. The animal fats and oils contain chiefly stearic, palmitic, oleic and linolic acids. Certain of the vegetable fats and oils, in addition to these, may contain lauric, myristic, capric and small quantities of other fatty acids. Soaps, therefore, are mixtures of the alkali salts of these fatty acids. The types and percentages vary with the fats or oils used in the manufacture of the soap.

Soap as it is marketed is not a simple mixture of the sodium or potassium salt of the higher fatty acids but contains a great many other substances, among them rosin, which may be present in quantities as high as 30 per cent. Sodium silicate, or water glass, may be present in poor soaps in quantities as high as 40 per cent. Sodium carbonate and trisodium phosphate are commonly present in soap powders. Naphtha and borax may be present. Numerous perfumes which are mixtures of essential oils, gums, resins, balsams and animal products such as ambergris, musk and civet, along with synthetic perfumes, are employed. Many of these compounds are well known eczematizing agents.

From the Department of Dermatology and Syphilology, University of Buffalo School of Medicine.

Read before the Section on Dermatology and Syphilology at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

1. Jordan, J. W.; Walker, H. L., and Osborne, E. D.: Studies in the Eczematizing Properties of Soaps, *New York State J. Med.* 36: 791-793 (May 15) 1936.

All soaps in aqueous solution undergo hydrolysis to a greater or lesser extent and thus are split up into free alkali and free fatty acid. The degree of hydrolysis depends somewhat on the fatty acids employed in the manufacture, the temperature of the solution and the concentration of the soap. Even a neutral soap, therefore, liberates free alkali when in solution. Some observers are of the opinion that specific hypersensitivity to alkalis is not uncommon. The fatty acids also in themselves are potential eczematogenous agents. Blank² found that fatty acids of low molecular weight, particularly those derived from coconut or palm kernel oil, were in themselves irritating to the skin and that the higher fatty acids, such as palmitic, oleic and stearic, in the presence of alkali were also irritating to the skin. Dermatitis from certain fatty acids has been reported from time to time in the literature.³

In this paper the term soap is employed in a broad sense and means the sodium or potassium salt of the higher fatty acids, together with any substances which may be added to the final product as marketed.

During the past four years we have observed 239 patients in private practice who had a dermatitis on the hands, with or without involvement of other areas, in whom soaps appeared to be the exciting cause. Of these patients 61 per cent were housewives or domestics doing general housework. The remaining 39 per cent were for the most part engaged in occupations that required frequent contact with soaps and allied cleansers. Among them were dishwashers, cooks, hairdressers, bartenders, surgeons, nurses and orderlies. All age groups were represented but most patients were between the ages of 20 and 40. The average period from the time of the first attack of dermatitis of the hands until the patient came under our observation was three years. The longest period was twenty years, the shortest one week. The group had used fourteen different toilet and fifteen different laundry soaps, flakes or powders. All had employed two or more and many several of these cleansers. We were unable to determine from their histories whether or not certain brands of cleansers were more apt to produce eczema than others.

Based on the histories of these 239 patients and on our clinical observations and studies, we believe that the following are the cardinal features of eczema due to soaps and allied cleansers: Most patients in whom the first attack of dermatitis appeared more than a year before they came under our observation noted that they were either completely free from the condition or improved during the warm months. A high percentage of the patients noted improvement during periods of vacation, illness or other lapses in routine when soap and cleansers were used infrequently. Many patients observed that an attack was precipitated or an existing dermatitis made worse when these substances were frequently used. Nearly all patients reported periods of exacerbation and quiescence, and many patients had periods of complete freedom lasting from a week to several years.

In most instances the dermatitis was vesicular and was confined to areas on the hands. In general it was worse on the right hand of right-handed women and on the left of left-handed women. It seldom involved the entire dorsal aspects of the hands. Most patients

had patches on the dorsum of the hands with involvement of one or more of the fingers. The interdigital areas were frequently involved, the palms rarely. The next most commonly involved area was the wrist. In a few instances the dermatitis spread to the forearms and arms and other areas uncovered by clothing. In such instances the flare-ups usually coincided with the doing of laundry or other work that involved the immersion of the hands and arms into solutions of soaps or allied substances. When the face was involved, the patient usually had been exposed to steam and fumes arising from hot solutions of these substances.

The eczema in many of our cases had been erroneously diagnosed as ringworm and nearly all long-standing cases had run the gamut of ringworm remedies. They were either unimproved or made worse by treatment of this type. The diagnosis in our cases was made by a carefully taken history including the duration of the condition, the frequency of exposure and the types of soap and allied cleansers employed in the household. The patients were carefully questioned regarding improvement when these substances were infrequently handled and whether exacerbations occurred following more than the usual degree of exposure. Many of the patients had been observed during several acute attacks. Most patients admitted that attacks came when they had become careless in carrying out preventive measures. All were questioned about contact with other eczematizing substances and these substances were ruled out as a cause of the dermatitis either by history, observation or patch tests, the limitations of the latter procedure being borne in mind.

Patch tests were done almost as a routine during the first two years of this study. We found that they were of very limited value as a diagnostic procedure in individual patients, since it was impossible to duplicate by patch test studies the actual conditions of contact. Such factors as the degree and frequency of exposure, which are of paramount importance in soap dermatitis, cannot be duplicated by patch tests. The alkali present in a drop of soap solution applied as a patch test is rapidly neutralized by the acids present in the sweat and, although we do not believe that alkali is the important eczematizing substance of soap, Blank² has shown that the fatty acids usually employed in the manufacture of soap are more irritating to the skin in the presence of alkali. Obviously, when the hands or arms are immersed in large amounts of soap and cleansers the alkali is not neutralized. We therefore have discontinued patch tests as a routine diagnostic measure in suspected cases and depend on the history and clinical observations.

In our previous communication¹ we expressed the opinion that eczematous responses to patch tests with soap solutions in dilutions greater than 1:100 in most patients represented an allergy to one or more of the ingredients of the soap to which the patient reacted. This view was based on the relative infrequency of eczematous reactions to dilute soap solutions among patients with normal skins and the frequency of reaction among those who had eczema. Later, Osborne and Walker⁴ in patch test experiments on the skin of newborn babies found that none reacted in an eczematous manner to a soap solution in a dilution of 1:100 and thus demonstrated that this dilution of soap does not

produce an eczematous response owing to primary irritation or inherent hypersensitiveness in the infant. Those reactions encountered in later life must therefore in most instances be due to a specific altered epidermal response that causes the skin to react in an eczematous manner to the ingredients of soaps. Patch tests when strongly positive (vesicular or papulovesicular) are of diagnostic value but many patients with eczema due to soaps proved by clinical observation give negative responses to these tests.

The allergic nature of eczemas due to soaps and allied cleansers was further demonstrated by clinical observation of our patients. Most had been using the same soap or cleanser for weeks, months or years before an eczematous dermatitis appeared. Following the appearance of the eczema, they were unable to tolerate to the same extent a preparation which previously had caused no difficulty.

METHODS OF PREVENTION AND TREATMENT OF SOAP DERMATITIS

During the first two and a half years of this study we attempted to allow healing of existing lesions and prevent recurrences of the dermatitis by instructing our patients to wear cotton gloves covered by rubber gloves whenever it was necessary to perform household duties that required the use of soaps or allied cleansers. The purpose of the cotton gloves was to absorb moisture and prevent irritation from rubber. We employed olive oil or liquid petrolatum to cleanse the affected areas of the skin, since there was no good detergent that was available as a substitute for soap. The only other measures employed were the use of simple soothing wet dressings, ointments or lotions, depending on the degree and severity of the dermatitis. Under this regimen the dermatitis in nearly all cases improved or disappeared. If definite improvement was not manifest at the end of two weeks, other possible undiscovered allergens were searched for as a cause. These measures were efficacious in controlling acute attacks of soap dermatitis. Most of our patients, however, found it impracticable to avoid soaps and allied cleansers for long periods of time and thus had recurrences. It was apparent that the only solution to the problem of soap dermatitis lay in the substitution of some soapless detergent that could be employed both for toilet and for general household use. Such a detergent, to meet all the requirements of a suitable substitute for soaps and allied cleansers, must itself have a low sensitizing index, be nonirritating to the skin, compare closely to soap in cost and have physical properties that permit it to be marketed in liquid, bar or powdered form. Blank² recently investigated and reported on the use of a mixture containing a sulfonated oil as a substitute for soap in cases of soap eczema. He found that the compound he employed was relatively nonirritating and had good detergent properties.

During the past sixteen months we have had 150 patients use this mixture as a substitute for toilet soap. Seventy-nine of these were housewives with eczema due to soaps. The remaining seventy-one patients had some other dermatoses. Many used the compound as a shampoo. Fifty-one of the seventy-nine patients who had a soap dermatitis were entirely free from the eruption or the eruption was greatly improved as long as they used only the oil and avoided all contact with soaps or allied cleansers. Twenty-six were not seen after the preparation had been prescribed and two of the patients had a

flare-up of the dermatitis following the use of the compound. Sixty-six of the seventy-one patients who had some dermatosis other than soap eczema and who used this compound tolerated it well. Four were not seen after the preparation had been prescribed and one tolerated it satisfactorily for four weeks, and then suddenly an acute dermatitis developed from its use. A patch test done with the oil was strongly positive. This was the only definite instance of allergy that developed among our 150 patients following the use of this sulfonated oil.

All the patients were satisfied with the cleansing action of the compound; many used it in a routine manner as a shampoo. Most patients, however, found it an unpractical substitute for soaps. Since it is a liquid, it is not suitable for the bath and it cannot be used for general household cleansing purposes. Its cost is prohibitive for long continued use as a substitute for toilet soaps by most patients. The preparation, therefore, fulfils only a few of the requirements for an ideal substitute for soaps and allied cleansers.

During the past year we have been investigating the alkyl sulfonates⁵ for their possibilities as substitutes for soap and household cleansers. These compounds can be made by the sulfonation of higher fatty alcohols derived from the fatty acids ordinarily used in the manufacture of soap or from cheaper substances such as petroleum derivatives. The compounds thus obtained are solids and therefore can be prepared in bar form for toilet use or in powdered form for general household cleansing purposes. They are neutral in reaction and do not hydrolyze as do soaps and can be used with either acids or alkalis. Their calcium and magnesium salts are soluble in water and therefore they leave no deposit of these salts as a scum in bathtubs, sinks or other receptacles and no greasy spots in clothing. They are much more effective as emulsifying and detergent agents than are soaps and are stable under ordinary atmospheric conditions. They do not oxidize or turn rancid as do soaps. These compounds can be prepared and marketed at a cost that compares favorably with soap and have been employed extensively in the textile industry as a substitute for soap with marked success.

Some of these compounds have been used during recent years as a substitute for soap in shampoos, tooth pastes and powders and liquid dentifrices. Kitchin and Graham⁶ investigated the alkyl sulfonates as a substitute for soap in dentifrices and found them superior to soap as a detergent. They noted no evidence of inflammation of the soft tissues of the mouth from their use. Epstein and his co-workers⁷ studied these compounds for possible toxic effects that might follow accidental ingestion of them. They found them as harmless as soap.

The foregoing makes it apparent that this group of compounds is an ideal substitute for soap in cases of housewives' eczema due to soap and allied cleansers from the standpoints of comparative cost and physical properties. We therefore have attempted to determine whether they had the other two requirements of an ideal

soap substitute; that is, whether they were nonirritating and had a low sensitizing index.

The alkyl sulfonate employed in this study is known chemically as lauryl sulfoacetate but, since pure lauryl alcohol is not available commercially, the compound, in addition to the chief ingredient, contains variable amounts of alkyl sulfonates derived from other higher alcohols present in the material from which it is synthesized. Patch test experiments were done with this compound on 150 patients to determine whether it was irritating to the skin. The tests were applied in dilutions of 1:10, 1:25, 1:50 and 1:100. They were left on the skin for twenty-four hours and read at the end of that time and again in forty-eight hours and seventy-two hours. Ninety of the 150 patients chosen had an eczematous dermatitis; the remaining sixty had no known allergic condition. A few of the subjects developed a mild erythema from dilutions of 1:10. These reactions were considered to be of no significance. Three of the ninety eczematous patients developed papular to papulovesicular reactions to one or more of the dilutions. One of these had a mild papular reaction to a 1:10 dilution and a mild erythema to the other dilutions; the other two had vesicular reactions to dilutions of 1:10 and 1:25 and papular reactions to dilutions of 1:50 and 1:100. One of these three patients had previously had a dermatitis from a shampoo containing an alkyl sulfonate. We were unable to elicit a history of any contact with alkyl sulfonates from the other two. None of the sixty nonallergic patients gave a positive reaction. The tests, therefore, demonstrated that in the concentrations employed the substance studied was not a primary irritant.

Patch tests of this type do not give an index of the sensitizing properties of the substances employed, since most of the subjects chosen may not have had previous contact with these compounds and therefore no opportunity to develop sensitization to them. To determine the cutaneous sensitizing index of a compound, it is necessary to use it on the skin for a variable period of time and determine whether a sensitization dermatitis ultimately results from repeated exposure to the substance.

There have been rare reports in the literature of dermatitis venenata from these compounds⁸ and prior to this study we observed two instances of sensitization dermatitis from their use. One patient developed a severe dermatitis from the use of a shampoo, and another from a tooth powder containing an alkyl sulfonate. However, considering the extent of the use of these compounds in the textile industry and more recently in shampoos, dentifrices and cosmetic preparations, with the paucity of reports in the literature of dermatitis from their use, they did not appear to be very active eczematizing agents.

We instructed twenty-seven patients who were allergic to soaps to use cakes made of the compound undiluted as a substitute for soap. Twenty-six of the patients tolerated the preparation satisfactorily. One of the group, a man who had polysensitivities, used the substance for two weeks and then a dermatitis developed from its use. A patch test was done with a 10 per cent solution of the preparation and a papular reaction developed at the end of twenty-four hours.

In addition to the compound containing lauryl sulfoacetate we have also been studying another of the alkyl sulfonates, aryl alkyl sulfonate. This alkyl sulfonate is manufactured from a petroleum derivative and is therefore much cheaper than the alkyl sulfonates manufactured from the fatty alcohols. The compound is markedly detergent and, because of its low cost, may be a suitable substitute for laundry soaps and for other general household cleansers.

The compounds mentioned are markedly efficient as emulsifying agents of cutaneous fats and, in full strength, are too detergent for the human skin. High concentrations produce excessive dryness of the skin through removal of cutaneous fats. To make a suitable toilet preparation, it is necessary to use these compounds in low concentrations in suitable vehicles. They can be put in aqueous solution and used the same way as liquid soap or in oil, or water in oil preparation, or they can be incorporated in a suitable nonirritating, water soluble, solid, inert substance. Our experience up to the present time indicates that 10 per cent lauryl sulfoacetate in a suitable vehicle is as detergent as most toilet soaps. In this concentration it does not produce excessive dryness.

While a certain number of patients undoubtedly will develop sensitization dermatitis from the prolonged use of these compounds, it is our opinion that they are not primary irritants or highly eczematizing in concentrations sufficient for cleansing purposes. Our studies lead us to believe that they come closest to an ideal substitute for soap that has yet been developed, since they compare favorably with soap and other cleansers in cost, they are solids and they can be used for toilet, laundry and general household cleaning purposes. They are nonirritating to the skin in concentrations sufficient for cleansing purposes and have a low sensitizing index.

SUMMARY

1. Soaps and allied cleansers are important causes of eczema of the hands in housewives or others whose occupations require frequent exposure to them.

2. The important clinical features of eczema due to soaps and allied cleansers include the following: (a) The eruption is usually vesicular with a patchy distribution on the dorsum of the fingers, hands and occasionally other exposed areas. (b) The eczema tends to improve in warm weather and in general is better or worse, depending on the degree and frequency of exposure to these substances. (c) Many of these cases are erroneously diagnosed as ringworm and unsatisfactorily treated as such.

3. Patch tests are of limited value in the diagnosis of individual cases, but when they are positive in dilutions of 1:100 or greater they indicate an allergy to one or more of the soap ingredients.

4. Methods of prevention and control depend on (a) avoidance of contact with soaps and allied cleansers, (b) local applications consisting of soothing wet dressings, lotions and ointments and (c) the use of suitable substitutes for soap and allied cleansers.

5. A sulfonated oil has advantages and disadvantages in comparison with the alkyl sulfonates as a substitute for soaps. We believe that the latter group of compounds, when used in suitable concentrations, most closely approximate the ideal soap substitute available at the present time.

ABSTRACT OF DISCUSSION

DR. JOSEPH V. KLAUDER, Philadelphia: I do not believe that the compound soap is allergenic. Excluding medicated soaps, the notable allergenic ingredients of soap are dyes, perfumes and essential oils. I believe the role that soap plays in the causation of dermatitis of the hands in housewives and others concerns the defatting action of soap but more especially the prolonged exposure to soap as an alkaline substance. Burckhardt's studies suggest that the eczematogenous action of soap is inherent to impairment of the function of the skin to neutralize alkali, whereby an alkaline reacting substance becomes an irritant to a concentration to which the normal skin does not react. Burckhardt called this toxic hypersensitivity. This serves, I believe, in explanation of the eczematogenous action of all alkaline cutaneous detergents. If a positive patch test to soap is an allergic one, it should be positive in a wide range of dilution of soap. It is desirable in a study of patch tests to soap to perform also tests such as Burckhardt outlined in the direction of determining if the function of the skin to neutralize alkali is impaired. In this way it could be determined whether a positive patch test to soap correlates an impaired function of the skin to neutralize an alkali. An important phase in prevention of dermatitis caused by prolonged exposure to soap, indeed to any alkaline cleanser, is to immerse the hands at the end of the work day in a 1-3 per cent solution of acetic acid, indeed vinegar. The authors studied the use as soap substitutes of some organic preparations that have wetting, penetrating, emulsifying or detergent properties. I believe that all such preparations exert a defatting action. The authors call attention to this and therefore advise their use in a diluted form. The authors have made a notable contribution in mixing these detergents in a nonirritating, water soluble substance, urea, in order to employ them in cake form. They have observed dermatitis—an allergic reaction resulting from an alkyl sulfonate and also from a sulfonated oil. Further use of these detergents will be required in order to determine whether the newer organic compounds are more allergenic than the sulfonated oils. An ideal cutaneous detergent should be neutral or on the acid side (about pH 5); it should not have a defatting action and should have no or a low allergenic property. I believe that the balance now is in favor of the sulfonated oils.

DR. MARION B. SULZBERGER, New York: I don't think that any dermatologist has doubted for the last two decades that many eczematous eruptions of various types are either caused by or aggravated by the use of soap. It is the practice of the majority of dermatologists with whom I have conversed on the subject to tell the patient with eczematous dermatitis of the hands that soap is bad for the skin. In my practice, I have emphasized this more strongly by telling the patient that for his particular hands "soap is poison" and that he must avoid soap the way he would avoid a real poison if he wants to get well. There are other dermatoses in which soap may be very harmful. For example, senile pruritus is certainly one such dermatitis; winter itch and bath itch are others, and notably infantile eczema and atopic dermatitis (disseminated neurodermatitis) in the child and in the adult are often harmed by soap. And in infantile eczema I believe the role of soap is just as important as it is in dermatoses of the hands. There is a large group of important skin disorders in which soap must be avoided. How does the soap act? I am inclined to agree with the authors and others who believe that there is a combination of alkali damage plus irritation or sensitization to some other ingredient in the soap. That is, the alkali damage to the skin more or less paves the way for the other effects of perfumes, of fillers, of fatty acids and of other substances which may be contained in the soap and paves the way for sensitization or irritation from other substances not contained in the soap, such as occupational substances and other contact agents. The chief problem for years has been to find a satisfactory soap substitute. None of the soap substitutes submitted for my trial among patients have been entirely satisfactory for several reasons aside from the possibility of their also causing irritations and sensitizations on their own part. One objection is that they have not as yet been put up in cake form. The cake is an actual convenience. It is difficult to get people to carry a container, as they must now do if they are obliged to use soap substitutes. Another reason is that these

substitutes cause no foam. People connect the foaming with the detergent effect, although of course this is not a necessary association. A third reason why patients do not like the present soap substitutes is that none of them leave that slippery feeling which people have been accustomed to associate with the feeling of cleanliness and of softness of the skin and which is due to alkali damage of the surface of the skin. The next difficulty is that these soap substitutes are not obtainable everywhere. People don't want to have to go to certain stores to get things. The fifth difficulty is the price. The soap substitutes are comparatively expensive at present.

DR. HERMAN GOODMAN, New York: The paper is restricted to conditions found in housewives. It is not impossible to find similar reactions in men. It is not the soap or substitute for soap which is at fault; the skin is the wrong soil for the soap. There are two kinds of skin. To bring the matter into the realm of soap making, I classify skin first as of the oil in water emulsion type. Normal soap is also of the oil in water emulsion type. If the patient's skin and the soap are both of the oil in water emulsion type, the patient's skin can tolerate the soap. Oil in water soaps are of two varieties: One is soluble, formed with fatty acid by univalent salts, as potassium, sodium and ammonium. The insoluble oil in water soaps are formed with fatty acid by bivalent salts, as magnesium and calcium. Many persons who tolerate soluble oil in water soaps react by evidence of skin irritation to insoluble oil in water soaps. It is held that the insoluble oil in water soaps are irritants to the skin of such people. The second kind of skin is regarded as the water in oil emulsion type, which does not tolerate oil in water phase soap. Every grandmother advised the substitution of oil for soap if a child did not tolerate soap and water. Substitution of oil in water emulsion type soap for another oil in water emulsion type soap does not relieve the person whose particular skin is of the water in oil emulsion type. Certain superfatted soaps were once available which purported to be in effect water in oil emulsion type. Many creams offered as a substitute for oil in water emulsion type soap are likewise oil in water emulsion type creams and are in effect conventional soap with high water content sold in a jar rather than the dehydrated oil in water emulsion type soap sold in cake form. The physician can learn only by trial and error whether his patient has the skin of the oil in water emulsion type or of the water in oil emulsion type.

DR. JOSEPH MULLER, Worcester, Mass.: On the practical side of this paper the question is what to do with the patient who has to use soap. In my experience it makes a great deal of difference how the soap is used, not only what soap is used. This holds true only with the patient who is in contact with soap for a comparatively short time. With the usual way of washing hands, for instance in hospitals, by nurses and orderlies and doctors, the trouble is that the soap remains on the hands after the washing is over; it is not thoroughly rinsed off. This way the irritating effect of soap lasts for a long time instead of a minute or two, as it would with proper rinsing. I think that, if we advise our patients to rinse their hands with lukewarm water very carefully after using soap, the milder cases of soap dermatitis will disappear without the use of substitutes instead of soap. The important thing is good rinsing with lukewarm water. Cold water does not dissolve the average soap and, of course, hot water causes inflammation by itself.

DR. ADOLPH ROSTENBERG JR., Washington, D. C.: Are most of the dermatitides which result from contact with soap predicated on a specific sensitization or on some other mechanism? This is an important point because it will shed light on broader questions of skin irritations and possibly lead to an understanding of some mechanisms of skin irritation which are poorly understood. I do not doubt that some cases of dermatitis which arise after contact with soap are predicated on a specific sensitization, but the weight of evidence points to the fact that the majority arise as a result of some other mechanism. In a paper presented before this section a few years ago by Dr. Sulzberger and myself on an analysis of patch tests, we reported that we had found a much greater incidence of positive patch tests to soap in atopic dermatitis than in cases of dermatitis venenata in which we had found the specific etiology. What does this mean? To me it is inconceivable that atopic dermatitis is predicated on a sensitization to soap. From all we know

of atopic dermatitis, it is not predicated on the epidermal type of sensitization at all. All the high incidence of reactions to soap in that type of dermatosis can mean is that those individuals have some functional abnormality of their skin which does not allow them to tolerate soap as do their fellow men. There is a great deal of ancillary evidence as well to show that their skin is not the same as the skin of other individuals. But what does the fact that the cases of dermatitis venenata did not give an inordinately high percentage of positive reactions to soap mean? Of course it can be argued that we just happened to fall on a group of individuals who had never become sensitized to soap. But assuredly those individuals had the opportunity to become sensitized to soap. It has also been shown that individuals who become sensitized to one eczematous allergen are much more prone to become sensitized to some other eczematous allergen. In view of those facts and of the work done by Burckhardt, all the evidence seems to point to the fact that reactions from soap are predicated on a mechanism other than a specific allergic sensitization. While I do not believe that this mechanism is understood at the moment, the importance of realizing this is to point out the direction in which further work should be continued.

DR. HOWARD J. PARKHURST, Toledo, Ohio: The authors mentioned that there were fewer of these cases in summer. That seems in line with observations of Hansen, who examined the p_{H} of the skin of the forearm after it had been washed for two minutes with toilet soap. He found that ordinarily it took three and one-half hours for the p_{H} of that area to return to normal, but only one-half hour if the patient was perspiring freely. Most observers feel that the free alkali itself is probably not an irritant but that it apparently prepares the skin for the action of various potential irritants such as those ingredients of soaps which the authors mentioned. I think we are agreed that some cleansing agent has to be used. Soaps or cleansing agents cannot be avoided, and I think we are also agreed that the offenders are a few of the stronger modern laundry soaps and the hard water toilet soaps chiefly, and also the water softeners. Sulfonated oil and sulfonated alcohol are of some value as substitutes, but I don't feel that they are as good cleansing agents as the soaps, and it has been shown that they themselves are occasional sources of irritation. Therefore I feel that it is better to substitute some milder soap. All are familiar with a number of them. And to use a better technic of washing or handling the soap, as has already been brought out in this discussion, in my experience has been all that has been required.

DR. DONALD M. PILLSBURY, Philadelphia: During the past year Livingood and myself have in about 200 cases employed various soap substitutes, wetting agents of various types incorporated in oils and with higher alcohols. We can confirm the value of such substitutes in cases of dermatitis of the hands, whether or not they seem to be due primarily to soap. They have been used in infantile eczemas and in ichthyosis. These compounds will often alone produce a satisfactory clinical improvement in ichthyosis which appears during the winter months. We have not encountered any particular evidence of allergenic capacity. I think that the final story as regards their allergenic capacity will not be told until a considerable number of persons have used these compounds over a long period of time.

DR. JAMES W. JORDON, Buffalo: It has been our impression from patch tests and other studies that the alkali present in soap is not the most important factor in soap dermatitis. The alkali, however, does pave the way by its degreasing action on the skin in permitting other allergens to sensitize the skin. If alkali alone were the cause of soap dermatitis, sulfonated alcohols would solve the problem since they contain no alkali and are neutral in reaction and do not hydrolyze. The sulfonated alcohols in undiluted form produce excessive dryness of the skin so that it is necessary to incorporate them in inert bases. So far, we have not prepared an ideal preparation but have been using a compound containing 10 per cent lauryl sulfoacetate, 88 per cent urea and 2 per cent unsulfonated lauric alcohol. The lauric alcohol causes a smooth satin-like feeling to the skin following the use of the compound. I agree with Dr. Sulzberger that there are many dermatoses in which soaps play an important part such as senile pruritus, winter itch and bath itch. We also

believe that many low grade eczemas are due to sensitization to insoluble soaps present in laundered materials. We agree with Dr. Goodman that the type of skin is of some importance in soap dermatitis. People with oily skins will tolerate soap better than those with dry skins. Ichthyotic persons tend particularly to develop soap dermatitis, sometimes in primary irritation and sometimes because of sensitization to ingredients of the soap. We believe that soap dermatitis is more common in the winter time because the skin is drier at that time. Regarding patch tests with soap solutions, we did 2,600 different tests some time ago, using various dilutions of soap, and our results do not agree with those of Dr. Rostenberg. We found that 50 per cent of all patients who had eczema developed strongly positive patch test reactions to one or more of the soaps to which they were tested. Furthermore, we found that most patients did not react to all of the soaps employed but usually to two or three, in spite of the fact that the alkali content of the soaps employed was approximately the same. This indicates that it was not the alkali present in the soap but perhaps a fatty acid or something else added to the soap that produced the reaction. We have used the so-called milder soaps and superfatted soaps and have been unsuccessful in controlling soap dermatitis.

SOME FACTORS AND OBSERVATIONS ON PREPARATION AND PRESER- VATION OF DILUTE PLASMA

G. F. BUSBY, M.D.

AND

W. L. TATUM, M.D.

SALISBURY, N. C.

The importance of whole blood transfusion as a therapeutic agent is well recognized and established. The important role played by plasma in transfusion has not been fully appreciated. In the past the major criterion for transfusion in the majority of institutions has been the need for erythrocytes. From the ever increasing reports in the literature it is becoming apparent that the therapeutic value of transfusion in the treatment of many diseases is derived largely from the plasma rather than from the red cells. Certainly in shock without hemorrhage,¹ in burns,² for restoration and maintenance of plasma protein,³ for administration of antibodies⁴ and even in severe hemorrhage⁵ the effectiveness of plasma cannot be questioned.

The necessary delay in securing a suitable donor or in cross matching "banked" blood, if it is available, vitiates the effectiveness of transfusion in dire emergencies. Blood transfusions can be carried out successfully in a great majority of hospitals and, under favorable circumstances, in the home. Yet there are a number of small institutions without adequate facilities for matching and transfusing blood. Transfusion in the home is, at best, tedious and complicated. The need is as great in the one institution as in the other. There-

fore the need for an effective immediately available substitute for whole blood makes itself apparent. To be most effective, stability and ease of administration, without special preparation at the time of need, are of paramount importance. We have endeavored to show in other publications⁶ that plasma is such a substitute. Reports in the literature of its extensive use in many different types of cases clearly indicate its effectiveness. Its simplicity of administration and freedom from reactions enhance its usefulness.

In 1936 we suggested the use of blood plasma as a substitute for whole blood.⁷ At that time we were unable to find a method for preparing plasma in sufficient quantities for clinical use. Our first problem was therefore to devise a suitable method of preparation. For a method to be satisfactory for practical clinical use it was of the utmost importance that it meet certain criteria, namely:

1. Ease of maintaining an aseptic technic.
2. Universal adaptability.
3. Simplicity (plus economy in raw material, time and effort).
4. Ease and safety of storage and transportation.

Our first concern was the sterile collection of blood. After much experimentation we became convinced that the most satisfactory collecting flask for whole blood would be one containing an anticoagulant in a vacuum. This would permit the aseptic collection of blood in an entirely closed system. The result of this experimentation has become commercially available.

A technic for the preparation of plasma was developed and a similar vacuum container adapted to its preservation. With the development of this equipment and technic the practical preparation of plasma can be successfully carried out even in small laboratories. It can be administered with the simplicity of other parenteral fluids in any institution or in the home. Storage under widely varying conditions has not influenced its usefulness, and transportation for long distances has been found possible.

Our original idea in 1936 was to suggest the preparation and preservation of undiluted, uncentrifuged plasma to be stored without a preservative. It was not long, however, until we found precipitation occurring. In addition, plasma so prepared proved difficult to administer. Often our preparations were unusually cloudy owing to the presence of large quantities of fat. This was particularly true when our donors had eaten heartily. Cloudiness often suggested contamination, making bacterial cultures imperative before administration.

We soon found that, by centrifuging, clear plasma could be obtained, and by using fasting donors the plasma would be relatively free of fat. However, this clear plasma developed a precipitate after a few days storage. Gross precipitation was delayed by dilution with physiologic solution of sodium chloride to approximately the original blood volume. It was noted that, when plasma was prepared from whole blood less than twenty-four hours after collection, precipitation often occurred relatively soon, even after dilution. This did not occur when older blood was converted. Consequently, we are now storing all blood before it is converted. Through personal communication we are under the impression that an explanation for this difference in behavior will shortly be forthcoming.

Hemolysis is insignificant in plasma prepared from blood stored for periods up to five days.⁸ Agitation of older blood results in an undesirable mixing of hemoglobin with the plasma. This can be prevented by transferring blood from the original container to centrifuge bottles without shaking.⁹ Our first preparations were made by aspirating the supernatant plasma from the centrifuge bottle into the storage container immediately after centrifugation. However, as our centrifuge came to rest, invariably there was a swirl of cells through the supernatant plasma. When the supernatant plasma was aspirated, these cells came with it. These few cells, though not sufficient to cause reaction, were eventually destroyed, producing undesirable color and increased precipitation. This difficulty was eliminated by placing the centrifuge bottles in the refrigerator for twelve hours after centrifugation before the supernatant plasma was aspirated.

By means of this technic and equipment, complete asepsis has been achieved without resorting to special precautions. One hundred and fifty consecutive tests for sepsis on plasma prepared without a sterilizing preservative yielded negative cultures. Some of these specimens of diluted plasma had been stored at room temperature for eighteen months. In spite of this record we felt that additional safety could be assured by the addition of merthiolate as a preservative. We have used as a routine 5 cc. of a 1 per cent solution in 500 cc. of diluted plasma, giving a final concentration of 1:10,000. The low toxicity of merthiolate and its effective germicidal action in protein mediums¹⁰ suggested its use. Observations in the literature, clinical trial and personal communication would all seem to justify this action. Plasma thus protected was inoculated with staphylococci and streptococci, stored at room and at refrigerator temperatures and was found to be sterile when cultured twenty-four hours after inoculation. Four bottles of plasma containing merthiolate in a concentration of 1:10,000 have been exposed to the air at room temperature for periods up to seven months. Frequent aerobic and anaerobic cultures have been negative.

The electrophoretic protein patterns of a year old diluted plasma were studied by Drs. Scudder and Longworth of the Rockefeller Institute. They found some changes in the albumin and in the alpha, beta and gamma fractions of the globulin. The significance of these changes is not apparent. Chemical studies were made at Presbyterian Hospital in New York on six specimens of diluted plasma preserved from forty-five to 145 days. These studies included determinations of potassium, sodium, ammonia, hydrogen ion concentration and sterility. They gave no evidence of deterioration with age. Hydrogen ion concentration studies on diluted plasma at Duke University gave a mean reading of 7.6.

A variety of diluents have been tried and the one which has been generally used is physiologic solution of sodium chloride. However, recent studies seem to indicate that a solution of 5 per cent dextrose in physiologic solution of sodium chloride possesses certain advantages over the simple saline solution. Preliminary observations indicate that it possesses greater inhibitory power as to the formation of color and precipitates in plasma stored at room temperature for some period of time.

8. Much of our plasma is salvaged from outdated blood from the blood bank. Fifty-eight specimens of blood have been shipped to us by bus or mail. All these have been converted to very clear, satisfactory plasma.

9. Containers will soon be available which will not require this transfer.

Objections to the dextrose content have been raised on the ground that it might slow absorption when given extravascularly. Frequent intramuscular administrations have been given without any obvious difference in rates of absorption.

In the course of our studies it has frequently been noted that when dilute plasma has been prepared containing hemoglobin and stored at room temperature there was a marked change in color drifting through various shades, finally stabilizing as a muddy, chocolate colored solution. An absorption spectrographic study identifies this shifting color as being due to the formation of methemoglobin. The addition of either sodium cyanide or sodium hydrosulfite rapidly converts the chocolate colored solution back to a clear pink, which is readily recognized as being a dilute solution of hemoglobin. These observations would seem to give positive evidence that the hemoglobin is oxidized to methemoglobin. It is interesting to note that as low a concentration as 0.2 per cent methemoglobin can be responsible for a very unsatisfactory looking product.

While the precipitate previously mentioned has not been positively identified, the studies to date indicate that it is essentially proteinaceous in character. After separation and washing three times with distilled water it gives characteristic protein reactions, is soluble in citric acid solution and remains in solution at a p_H of 5. It is appreciably soluble in dilute alkalis. Colorimetric tests for albumin and globulin indicate their presence in only minute quantities. Nitrogen determinations on this precipitate dried at 60 C. gave a value of 12.48 per cent. The addition of calcium chloride to the supernatant dilute plasma from which

Approximate Age of Plasma When Administered

the precipitate had been removed by centrifugation results in no clot formation. While this precipitate has not been positively characterized, as a result of the foregoing observations it would seem reasonable to assume that it is fibrin. We are continuing our studies in an effort to identify this material positively.

Storage at refrigerator temperature is unquestionably optimum for plasma just as it is for whole blood. We have purposefully used plasma stored at room temperature for long periods of time to prove that it will not deteriorate, develop toxic products or lose its therapeutic effectiveness. We, of course, recognize the diminution, if not loss, of antibodies under these storage conditions and, consequently, make no claim as to its efficacy in the field of immunology after such storage. This study included fifty-three administrations. No reactions occurred. The storage period ranged from one to 270 days.

We wish to make a special note of the fact that five of the specimens of plasma traveled 17,000 miles in the United States and South America during a period of two months, starting the latter part of September 1939, and were subsequently stored in our laboratories for an additional four months. At no time during this period were these specimens protected from weather or climatic changes. A moderate precipitate and change in color were noted. Aerobic and anaerobic test cultures of two bottles were found to be sterile. The others

were not cultured. Their therapeutic effectiveness is illustrated by the following case:

A middle-aged Negro was admitted to the Rowan Memorial Hospital, Salisbury, N. C., moribund and suffering with extensive gangrene of the penis, scrotum and lower part of the abdominal wall. He was unconscious and showed all the signs of having an advanced circulatory failure. Survival for more than a few hours was not expected. He was given within thirty hours eight bottles of diluted plasma, each representing the plasma from 500 cc. of blood. This included the five bottles previously mentioned and an additional three bottles which had been exhibited at several medical meetings and had been stored at room temperature for more than nine months.

Restoration of blood pressure, lowering of temperature, decrease in pulse rate, increased urinary output and a return to consciousness followed. Within twenty-four hours he was able to take nourishment and survived eighty-four hours. The recipient's blood belonged to blood group A and all the plasma was from blood belonging to group O. No unfavorable reaction of any kind occurred during this therapy.

Our observations have been confined to the preparation and preservation of dilute plasma. We have had no experience with the lyophile method of Florsdorf and Mudd,¹¹ the concentration method of Thalheimer¹² or the drying in a vacuum at body temperature method of Edwards, Kay and Davie.¹³ All these methods have been reported as being highly satisfactory. The observations herein reported would not be applicable to their procedure.

CONCLUSION

In the past several years we have given 482 infusions with dilute plasma and have had but three reactions. In each instance in which untoward results were experienced they were unquestionably identified as being pyrogenic and caused by improper cleansing and preparation of the accessory equipment.

It is perhaps noteworthy that we have given plasma by means of the intravenous, subcutaneous and intramuscular routes, in some conditions with apparent equal clinical benefits. All plasma has been given with a recipient set containing a stainless steel filter which contains a 200 mesh stainless steel filtering cylinder. This cylinder removes all particulate matter of a magnitude greater than 74 microns in diameter.

A clear, dilute plasma in which little or no precipitate forms can be prepared by observing a few, simple precautions, namely:

1. The use of fasting donors.
2. The storage of whole blood for more than twenty-four hours before being converted to plasma.
3. The avoidance of shaking whole blood before it is transferred to centrifuge bottles.
4. Refrigeration for approximately twelve hours to permit sedimentation of red cells not removed by the centrifuge.
5. The use of a diluent containing dextrose.
6. The addition of merthiolate to a concentration of 1:10,000.

Dilute plasma prepared by our method is an effective substitute for whole blood. It is easily prepared. It is adaptable to all institutions. It has been administered safely and effectively after storage for periods up to nine months. Clinical use after storage under widely varying conditions, both in the home and in the hospital, indicates that it is a valuable and safe therapeutic agent.

Clinical Notes, Suggestions and New Instruments

ACUTE APPENDICITIS AND PINWORM INFESTATION OCCURRING CONCOMITANTLY IN THE SAME FAMILY

VICTOR MAYER, M.D., WARREN, PA.

The etiologic relationship of infestation with *Oxyuris vermicularis* to acute appendicitis in children has been shown frequently, though there is no ready agreement as to whether the parasite is to be considered the direct agent or concomitant and coincidental.

Dean Lewis,¹ in discussing this problem, finds that the parasite is found in apparently normal appendixes, in the sub-mucosa as well as between. He suggests the possibility that the parasites often penetrate the mucosa and that this may be the starting point of an acute attack.

While infestation of entire families and institutional groups is not uncommon and while a so-called family tendency to acute appendicitis is known, the combination of the two in one family over a short period of time bears reporting.

The family is of Italian descent and lives in poor circumstances. The mother, Mrs. V. T., aged 34, was first known to be infested at the time of delivery of her seventh child in 1935. At this time the diagnosis of *Oxyuris* infestation was made on gross examination when she passed many parasites at delivery and in the puerperium. She received subsequent treatment for this but was not followed up.

The members of the family are Mr. T. aged 40 (?), Mary aged 15, Tony aged 14, Charles aged 12, Frances aged 9, Anna Jean aged 8, Nicholas aged 4 and Nicholas aged 6 at the time of his death eleven years before. (The cause of death cannot be determined exactly—said to be appendicitis.)

REPORT OF CASES

The following are the members of the family who have been seen so far:

CASE 1.—F. T., a girl aged 9 years, was admitted Dec. 13 1939, with a history of "pain in the stomach" beginning on the evening of Dec. 11, 1939. The next day she complained of pain in the right side. This persisted to the time of her admission. There was no nausea or vomiting associated with the attacks of pain.

The past history was negative. (It was later learned from the patient that she had perianal itching, particularly at night.)

The patient had mild pharyngitis. The heart and lungs were normal; the liver and spleen were not palpable. There was tenderness over McBurney's point and localized rigidity over this area. Pressure on the left upper quadrant produced pain in the right lower quadrant. The temperature, pulse and respiration were normal.

A blood count showed 4,850,000 red cells, 9,300 white cells and hemoglobin content 100 per cent; differential: polymorphonuclear leukocytes, segmented 36 per cent and nonsegmented 2 per cent; lymphocytes 54 per cent, eosinophils 6 per cent and transitionals 2 per cent. The urine was acid, with a specific gravity of 1.007, and reactions for albumin and sugar were negative. Microscopic examination revealed occasional epithelial cells, from 12 to 15 red blood cells per high power field, no casts and an occasional leukocyte. Eosinophils were not explained by the studies done. There was no urinary complaint. Because of the persistence of pain and tenderness that the patient suffered on admission, an appendectomy was done December 14. At operation the mother's history was recalled. The appendix was long, inflamed and retrocecal, with dense adhesions, particularly at the midportion, producing sharp angulation.

When the appendix was opened, a foul odor was obtained and it was found to be full of pinworms actively motile in a mucopurulent fluid.

A specimen of urine taken on the first postoperative day showed very few red blood cells and an occasional epithelial cell; otherwise it gave negative results.

The patient was discharged on the ninth postoperative day after a course of *santonin* and mild mercurous chloride. When she was seen two months later she had no further complaint.

CASE 2.—C. T., a boy aged 12 years, a brother of patient 1, was admitted Jan. 8, 1940, approximately two weeks after his sister's discharge, with a history of pain in the right side for two days. He had a nasal discharge and perianal itching at night. There was no nausea or vomiting. The past history was negative.

The patient had acute rhinitis and acute myringitis. The heart and lungs were normal. There were tenderness in the right lower quadrant of the abdomen over McBurney's point as well as over the ascending colon and slight rebound tenderness at the right lower quadrant. There was no demonstrable rigidity.

A blood count showed on admission 9,400 white cells; differential: polymorphonuclear leukocytes, segmented 40 per cent, nonsegmented 1 per cent; lymphocytes 46 per cent, eosinophils 13 per cent.

Analysis of the urine was negative. The temperature, pulse and respiration were normal.

Knowing the history of family infestation, a conservative plan of treatment was instituted. Immediately after admission hypertonic saline enemas were given and particular attention was paid to the hygiene of the hands and the perianal region.

On the day after admission, January 9, a blood count showed hemoglobin content 92 per cent, 6,450,000 red cells, 18,500 white cells; differential: polymorphonuclear leukocytes, segmented 74 per cent, nonsegmented 8 per cent; lymphocytes 18 per cent, eosinophils 2 per cent. The temperature, pulse and respiration were normal. There was no increase in the complaints concerning the abdomen. January 10 a blood count showed 10,300 white cells; differential: polymorphonuclear leukocytes, segmented 64 per cent, nonsegmented 4 per cent; lymphocytes 28 per cent, eosinophils 2 per cent, transitionals 2 per cent.

Ova were not demonstrated in the feces. Mucus and blood were present.

Because of the persistence of the abdominal complaint and improvement of the infection of the upper respiratory tract, an appendectomy was performed the next day and revealed the appendix with a short meso-appendix injected, full and tense. Parasites were not found in the opened appendix.

Convalescence was interrupted by a hematoma in the incision. The patient was discharged on the fifteenth postoperative day.

CASE 3.—T. T., a boy aged 14, was admitted on the evening of Feb. 5, 1940, approximately two weeks after discharge of his brother C. T.

Approximately five days prior to admission the patient had a "stomach ache" but no nausea or vomiting, and his appetite was poor. This persisted until the day previous to his admission, when he began to complain of pain in the right side. No nausea or vomiting developed. Pain persisted until the time of his admission. There was a questionable history of nocturnal perianal itching. The patient had fallen several years previously and suffered injury of several fractured ribs.

The patient was underdeveloped with adenoid facies. The heart and lungs were normal. There was abdominal tenderness over the right lower quadrant and localized rigidity in that area. The temperature, pulse and respiration were normal.

A blood count showed on admission 7,400 white cells; differential: polymorphonuclear leukocytes, segmented 42 per cent, nonsegmented 4 per cent; lymphocytes 52 per cent, basophils 1 per cent, eosinophils 1 per cent.

Operation was postponed because there was improvement in the patient's condition. A blood count the next morning showed 5,100,000 red cells, 8,350 white cells, with the following differential: polymorphonuclear leukocytes, segmented 40 per cent, nonsegmented 6 per cent; lymphocytes 48 per cent, eosinophils 5 per cent, basophils 1 per cent.

Analysis of the urine showed a faint trace of albumin and occasional leukocytes.

Because of recurrence of symptoms and abdominal manifestations the patient was operated on. The appendix was found

From the Warren General Hospital.

injected, 3 inches long, full and tense. It was freely movable. When the appendix was opened many live pinworms were found present.

Convalescence was uneventful. The patient was seen one month after discharge and was free from complaints.

In view of the presence of infestation in the family two of the remaining children were seen and blood counts were made. They were free of any complaint.

A blood count of M. T., aged 15, on February 13, showed 8,200 white cells; differential: polymorphonuclear leukocytes, segmented 51 per cent, nonsegmented 1 per cent; lymphocytes 46 per cent, eosinophils 2 per cent.

A blood count of N. T., aged 4 years, February 13, showed 8,350 white cells; differential: polymorphonuclear leukocytes, segmented 40 per cent, nonsegmented 6 per cent; lymphocytes 48 per cent, eosinophils 5 per cent, basophils 1 per cent.

Several weeks later the father was seen in the outpatient department with the complaint of vague abdominal pain. Examination gave negative results. Laboratory studies were also negative. He was seen the next day with similar complaints and reexamination gave no positive evidence of abnormality and he was sent home.

CONCLUSIONS

Several members of the same family suffered from Oxyuris infestation and acute appendicitis concomitantly.

Pinworm infestation should be considered in acute appendicitis in children. Eosinophilia with a suggestive history of perianal itching should be looked for.

NEW LIGHT ON THE MECHANISMS BY WHICH NERVOUSNESS CAUSES DISCOMFORT

CLINICAL LECTURE AT NEW YORK SESSION

WALTER C. ALVAREZ, M.D.

ROCHESTER, MINN.

One of the hardest jobs I have to do several times each day is to convince a patient with functional troubles that all the symptoms are due to a nervous interference with the functions of a normal heart and a normal digestive tract. Some of these persons will, of course, have noted that their troubles followed a nervous shock or a period of overwork, insomnia, anxiety or sorrow, and for them it will be easy to accept my diagnosis and my suggestion that they see first what the effects of reassurance and a rest will be; but others who have broken down nervously without obvious cause will be hard to convince. If to these persons I do not give plausible explanations for their symptoms, using simple speech and simple illustrations, and if I cannot patiently and convincingly answer all their objections, they will only move on to consult another physician.

Often also, while talking to the physician who referred the patient, I find it hard to get him to see how unlikely it is that the symptoms complained of could all be due to the ptosis, "colitis," low blood pressure, low blood sugar or low basal metabolic rate which he found. Unfortunately, little in the training that we physicians received in college and mighty little in the information that we have since found in books and articles has prepared us for the idea that the brain, all by itself, is commonly out of order and that disturbances in the

nervous system can account for many of the syndromes that we see every day.

Obviously then the physician who wants to convince his colleagues and his patients of the functional and nervous nature of a number of common syndromes must not only make positive statements but be able to back them up with physiologic facts. Usually the patient, let us say a woman, denies that she is nervous, and commonly she is correct when she protests that she is intelligent, sensible and externally calm. She never was flighty or hysterical in her life, and she knows of no cause for a neurosis: she has a devoted husband, a happy home, ample means and nothing to worry about. Furthermore, as she says, how can her "storms" be of emotional origin when some of them come out of a clear sky, as when she is asleep or happy or perhaps on a vacation?

Symptoms Due to an Unstable Autonomic Nervous System.—Often, as I listen to the stories of these patients, it seems to me that their symptoms can most easily be explained as due to an instability of the autonomic or involuntary part of the nervous system which causes it to play disconcerting tricks on the heart, blood vessels, digestive tract, kidneys and skin. There will be attacks in which the patient will suffer with one or more of such symptoms as dizziness, faintness, trembling, jitteriness, chilliness, flashes of heat, flushing of the skin, sweating, waves of gooseflesh, palpitation, rapid or irregular heartbeat, air hunger, quivering in the abdomen, intestinal cramping, diarrhea, urticaria, bloating, frequent urination, perhaps a closing up of the nasal passages, and fear of impending disaster. Several of these symptoms are obviously those which would result from a stimulus spreading out through the sympathetic nerves and causing an outpouring of adrenin and sympathin. Others are due to stimulation of the parasympathetic nerves—the vagi and the sacral autonomies—and some are due to an outpouring of histamine, such as occurs in allergic persons.

If it is true, as physiologists now tell us, that there is a center in the brain which in health controls the autonomic nerves, the internal secretions and the involuntary organs so efficiently that we humans don't even know we have such things, then it would appear that in certain persons this center must function badly. But where is this center and why, at times, do storms come out of it?

HOMEOSTASIS AND THE HYPOTHALAMIC NUCLEI

Much of the answer we want can be found in the writings of Cannon,¹ who for years has been studying what he calls homeostasis, or the way in which the functioning of the several automatic organs of the body and the compositions of the several body fluids are kept within certain narrow limits. As he has shown, most of this vitally essential work is done by the sympathetic nervous system, which in turn is controlled by a sort of thermostat situated in the hypothalamic nuclei at the base of the brain. As Cushing once said, "Here in this well concealed spot . . . lies the very mainspring of primitive existence—vegetative, emotional and reproductive."

Here is the center that maintains body temperature by integrating the actions of the vasoconstrictors, the vasodilators, the sweat glands, the gooseflesh-making muscles, the somatic reflexes which bring about shiver-

ing and panting, and the mechanisms which regulate water metabolism and control urinary secretion. In addition, the hypothalamus has much to do with the deposition of fat, sexual development and the regulation of the breathing, the pulse rate, the cycle of sleep and waking, and the menstrual rhythm.

The Primitive Brain and Its New Control.—These are the functions we might expect this region to have when we remember that it represents the brain of those lowly ancestors of ours who crawled about in the mud millions of years ago, fighting for their food and their mates instinctively and without much will or choice. Gradually through the eons there developed those higher parts of the brain with which man now thinks and wills and remembers. In the normal adult these new higher parts keep the old lower ones under control, a control which was acquired partly during the ages and partly during the childhood of the individual. As every one knows, the small child behaves like an animal, snatching what doesn't belong to him, striking at his playmates, soiling himself, eating disgustingly and from time to time screaming with rage or fear. Only gradually does his cerebral cortex take over control as he learns to be more or less civilized. But even after he has become a gentleman, just let his cortex lose control, perhaps as he inhales some ether or after he drinks a pint of alcohol or gets into a rage, and again he may become a fighting beast. Or let the higher control be removed by a series of small strokes or by the widespread cortical degeneration that goes with senility or certain types of insanity, and again there may be left only a disgusting and irascible animal (Jackson,² Head³).

Storms That Come Out of the Uncontrolled Hypothalamus.—Interesting in this connection is the work of Cannon and Britton,⁴ Bard⁵ and others, who have shown that, if in an animal one removes the cerebral cortex so as to free from control the hypothalamus, the nuclei there will from time to time send out discharges which will cause the animal to go into attacks of cowering fear or of blind rage. Signs of great anger can be induced by merely touching the animal or picking it up, and they can be induced by stimulating the nuclei electrically. That this type of reaction can occur also in man was noted by Cushing in the case of a girl who had just had a glioma removed from the neighborhood of the hypothalamus. At the least touch she would become enraged.

At operations done on this region in men and women under local anesthesia the mere brushing away of blood may cause a maniacal reaction. Electrical stimulation of this region in conscious patients can produce a slowing of the heart, drowsiness, changes in blood pressure and respiratory rate, and feelings of anxiety. In animals such stimulation causes, besides the symptoms already mentioned, stoppage of the movements of the digestive tract.

The virus of the common type of encephalitis is particularly prone to attack the hypothalamic nuclei, and then some of the symptoms are somnolence and perhaps

later insomnia, perhaps an agitated depression, difficulty in concentrating, attacks of anxiety, loss of appetite, fluctuations in weight, perhaps chilliness, air hunger, sweating, lacrimation and salivation and, in women, amenorrhea.

A Possible Explanation for Nervous Storms.—We have here, then, in all these observations, suggestions for the explanation of many of the disturbing symptoms which we physicians see every day. Obviously, of course, much is as yet theoretical, and no neurophysiologist would think of claiming that all the symptoms described can come out of only these particular centers in the hypothalamus. There are many other centers for emotional reactions, and activities in the cortex can also be associated with disturbances in the emotions and in the behavior of the autonomic nervous system. For instance, as a tense nervous student writes an examination paper perspiration may pour out of his right axilla and water may flow copiously from his kidneys.

It seems highly suggestive, however, that when through fatigue or disease the control which the cerebral cortex normally exerts over the hypothalamic centers is removed, or when these centers are affected by local disease, storms can go out along the autonomic nerves and homeostasis can be rendered so inefficient that the victim becomes painfully conscious of the workings of his formerly quiet organs. It is known today that even the amount of fatigue that follows the loss of a night's sleep or a little dissipation or a cold can so interfere with the prompt adjustments that an aviator's nervous system must make to the lowered supply of oxygen that is encountered at high altitudes that, for a day or two, he had better not take out his ship.⁶

As every physician knows, many of the patients whose centers for homeostasis are out of control and whose autonomic nerves are misbehaving have been through enough strain, overwork or sorrow to tire the brain severely, and as C. M. Child has shown repeatedly, under adverse influences it is the higher centers that suffer first and to the greatest extent. In the badly fatigued person, then, it may be that the jitteriness, the increase in irritability, the insomnia and the tendency to flare up angrily or to worry pathologically are due largely to the escape from control of hypothalamic centers.

Equivalents of Insanity.—When the curious autonomic storms come in a person who has not been under any obvious strain I always think first of the possibility that some hereditary nervous taint which in other members of the family has produced insanity or epilepsy has in this person injured the centers that keep the involuntary nerves working smoothly and quietly. Actually one has only to study the members of a few families blighted by mental disease to find several persons with these queer stormy syndromes which are not described in textbooks and are therefore not well understood by the medical profession.

A Relation Between Nervous and Endocrine Diseases.—Another thing that through the years has impressed me about families with a nervous taint is that while some of the members have nervous troubles others have endocrine disturbances with perhaps poor sexual development, and others have curious mixtures of nervous and endocrine deficiencies. To me this is understandable now that it is known that injury to a

part of the brain, the hypothalamus, through its influence on the pituitary gland, can produce a fat sexless boy or a hairy girl who does not menstruate properly. As Foster Kennedy has said, formerly one wondered if a certain girl's failure to menstruate properly produced her psychopathy, but now it is obvious that all her troubles can come from one injury, and that to her brain. One can now see also why, in many of these cases, no amount of treatment with desiccated glands helps.

Encephalitis.—As I have already noted, the virus of encephalitis has a tendency to attack the centers in the hypothalamus, and for years I have suspected that mild infections of this type are responsible for some of the nervous breakdowns for which there is no discoverable cause, for some of the states in which the patient feels toxic and without his usual sense of well-being, and for some of the syndromes characterized by nervous storms. This idea is not so improbable now that it is known that many animals carry latent in the brain an encephalitic virus, and that many human beings carry the related herpetic virus. In these persons the least infection that lowers resistance will bring the blisters out around the mouth.

To me it is suggestive that injury wrought in the hypothalamic nuclei by a virus tends to produce either somnolence or insomnia and that these nuclei are particularly subject to depression by the barbiturate derivatives which are used so much today for the production of sleep. It is probably more than a coincidence that it is just the psychopathic or markedly fatigued person whose nerves are playing tricks on him who does not respond well to the barbiturates; in him they often produce only an unpleasant form of stimulation. Perhaps this indicates again that in these persons there is something wrong with the hypothalamic centers. Perhaps also there is a connection between this something wrong and the insomnia that so many of the patients with nervous storms complain about. Curiously, morphine often has an excitant effect on these persons similar to that which is seen regularly in cats, and now W. E. Hambourger has found that this peculiar effect comes out of the hypothalamus.

Small Intracranial Thromboses.—In older men and women another conceivable cause for an upset in the functions of the hypothalamic nuclei is injury wrought by one or more of those small thromboses that develop so commonly in cases of intracranial arteriosclerosis. Whenever in an older person a nervous breakdown comes suddenly with curious storms and a loss of all joy in life, one must strongly suspect a vascular injury to the brain. Unfortunately, few physicians think of this when, as so commonly happens, there is no weakening of arm or leg.

A Laboratory Test for a Defect in Homeostasis.—Interestingly, one can easily detect a failure in homeostasis, and one can sometimes recognize the type of person who is likely to have nervous storms, simply by comparing the results of tests made on the first day of an examination, when the patient was excited and worried, with the results of the same tests made later when the patient was mentally relaxed. Often as I have protested against the modern tendency of physicians to make diagnoses purely on the basis of laboratory reports, I have said that there is no laboratory test that will show that the patient has a psychosis, an unhappy love affair or a domineering mother-in-law, but to some extent I was wrong because often I

recognize a nervously unstable patient from a glance at the record of the examination. If I find that on two days the figures for blood pressure, temperature, basal metabolic rate, pulse rate, leukocyte count and blood sugar were practically the same I assume that the patient is fairly stable, but if I find that on the first day the figures were all abnormally high and on the next day they were normal, I am fairly certain that I am dealing with a somewhat unstable and apprehensive person.⁷

THE HORMONAL THEORY OF NERVOUS TRANSMISSION

So much for an explanation of the way in which storms can arise in the hypothalamus to plague and torment a tired or nervous or psychoneurotic or menopausal person. Now let us look at some other recent advances in physiologic knowledge which throw light on the mode of production of the symptoms after the storm starts. I refer to the recently discovered fact that, when one stimulates autonomic nerves, powerful drugs are set free at their endings, drugs which produce the observed effects on heart, intestine, blood vessels and skin.

Out of the vagal and sacral autonomic endings comes acetylcholine, which slows the heart, dilates the blood vessels and causes sweating, and out of most of the sympathetic nerve endings and out of the adrenal medulla comes adrenin, which makes the heart palpitate and sends up the blood pressure. The structures which are brought into action by the sympathetic impulses elaborate sympathin, which, in some of its actions, resembles adrenin. Other nervous influences cause outpourings of histamine, which appears now to be responsible for many of the symptoms of allergy. Interestingly, it has been shown in normal students that the injection of acetylcholine will cause changes in the mucosa of the bowel similar to those of the so-called mucous colitis which plagues most nervous women.

To me these facts are most useful because with them I can bolster up the self respect of the woman whose nerves are playing unpleasant tricks on her and frightening her badly. No longer need she feel on the defensive when her physician tells her that no organic disease can be found to explain her miseries. There can be no question now about the fact that her symptoms are real and just as disturbing and alarming as those that might follow if a physician were to inject into her veins a big dose of acetylcholine or adrenin or any other powerful drug. No one can blame her for being distressed and frightened, and no well informed person should ever think of telling her to forget it or to snap out of it. As I say to such a woman, "If I were to put a pint of whisky into you by stomach tube, no one could blame you for getting drunk, and you would have no reason for being ashamed of your behavior."

Probably luckily for us, acetylcholine is destroyed in the body almost as fast as it is formed, but unfortunately this is not true of the other hormonal substances. In ages past when a man became excited and his life depended on his ability to strike down an enemy or to beat him in a foot race, the outpouring of adrenin was useful because it helped the muscles to contract, and it delayed the coming of fatigue. During the ensuing fight or flight the adrenin was burned up, and hence it didn't stay in the man to plague him. The

7. The literature on this defect in homeostasis in the psychoneurotic is well reviewed in pages 623 to 626 of Bodansky, Meyer, and Bodansky, Oscar: *Biochemistry of Disease*, New York, Macmillan Company, 1940.

trouble today is that when persons get angry or frightened they commonly sit still and fight only with words or thoughts, and the powerful chemical hormones set free are only slowly destroyed. Perhaps now we have an explanation for the fact that exercise and physical work will often steady nervous persons and make them feel well. In women at the menopause exercise may temporarily put a stop to the flashes, perhaps by burning up the hormones that from time to time are being liberated in the body because of a poorly adjusted "thermostat."

SUMMARY

The physician's hardest job often is to convince a patient with functional troubles that all his symptoms are due to the misbehavior of nerves connected with a tired brain. The physician who expects to convince such a patient and to stop him from going the rounds of consultants' offices must have good and scientific explanations for the symptoms.

Most of the symptoms of these persons suggest an instability of the involuntary nervous system which causes it to play disconcerting tricks on a normal heart, blood vessels, digestive tract, kidneys and skin. The symptoms suggest storms running out along the autonomic nerves.

In the normal person there is a sort of thermostat situated in the hypothalamic nuclei at the base of the brain which controls the involuntary nerves and the glands of internal secretion so perfectly that the organs of the body function silently: so silently that the owner is unconscious of them. Normally this "thermostatic center" is kept in control by the cerebral cortex. When this control is removed in any way, the center works erratically, and storms go out to cause upsets in the functions of many of the organs of the body.

The "thermostatic center" can be upset by fatigue, insomnia and nervous strain. In many persons it behaves erratically because of a bad nervous inheritance, an inheritance that may have produced insanity, equivalents of insanity or abnormalities in sexual development in other members of the family. The center may be injured also by an encephalitic virus or in older persons by little thromboses due to arteriosclerosis.

When the storms come out of the brain along the involuntary nerves, at the ends of these nerves are formed powerful chemical substances which have disturbing effects on most of the organs of the body. This means that the patient need not feel embarrassed about telling of his symptoms. When the storm comes and the powerful hormones are injected into him by his nervous system, he can no more avoid having alarming symptoms than he could avoid getting drunk if some one were to force a pint of whisky down his throat.⁸

Special Article

THE PHARMACOPEIA AND THE
PHYSICIAN

LEUKORRHEA

CLINICAL AND THERAPEUTIC ASPECTS

P. BROOKE BLAND, M.D.

AND

ABRAHAM E. RAKOFF, M.D.

PHILADELPHIA

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopoeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.

Basically, leukorrhea is a symptom, not a disease. Subjectively and objectively it is an expression of some underlying disorder, either functional or organic. Though the symptom may arise from a variety of constitutional or systemic conditions, it has its origin, in most instances, in some lesion of the reproductive organs. The symptom may appear at any age, as in infancy, in childhood, in the child bearing period, in the menopausal years and during senescence.

Although leukorrhea may be an accompaniment of many local and systemic diseases, it is a predominant symptom in a particular group of diseases. It must always be borne in mind, however, that leukorrhea may be the symptom which, if properly investigated, will lead to the discovery of more serious lesions, such as neoplasms, syphilis, tuberculosis and a host of other diseases.

The treatment of leukorrhea is no longer palliative but rather therapy is directed at specific disease entities. This change has been brought about by a better understanding of the various endocrine factors which control the biologic characteristics of the vagina and cervix, plus a better appreciation of the significance of various organisms present in the lower genital tract. It is now well established that the cyclic proliferation of the vaginal epithelium and the deposition of glycogen in its cells are under the direct control of ovarian estrogenic activity and that these factors in turn influence the pH of the vaginal secretion and its flora.

Thus, in arriving at an etiologic diagnosis in a case presenting an increased vaginal discharge, one or more of the following procedures are usually required:

1. Fresh wet smear examination of the vaginal and cervical discharge. Dark field examinations are sometimes necessary.
2. Gram-stained smears. Occasionally special stains may be required.
3. Routine or special cultures.
4. Evaluation of the cellular content by smear methods as an indicator of estrogenic activity. Biopsy may also be employed.
5. Determination of the pH of the vaginal and cervical secretions, either with indicator papers or, preferably, with a pH meter.
6. Biopsy for histologic diagnosis.

CERVICAL INFECTIONS

Infections of the cervix constitute a common cause of leukorrhea. The deep-branching glands of this structure form an excellent nidus for various bacteria, which may gain entrance to the genital tract and result in deep-

seated chronic infections, of which persistent leukorrhea is a prominent symptom. Cervical infections may result from primary invasion with a specific organism, notably the gonococcus, or may be caused by invasion of a variety of organisms following postpartum, postabortal or instrumental trauma.

Acute Stage.—In the acute stage of cervical infections the treatment of the accompanying leukorrhea is overshadowed by efforts to prevent the extension of the infection to the uterine cavity and the structures beyond, either by direct extension or through the lymphatics.

The treatment is entirely along medical lines and is directed toward the rest of the infected tissues, local cleanliness and the establishment of proper drainage.

Vulvar irrigations ("pitcher douches") three or four times a day afford much relief and are of hygienic aid. A saturated solution of boric acid or compound solution of iodine, 1 drachm (4 cc.) to 2 quarts (liters) of warm water, may be used for this purpose.

If the discharge is especially malodorous, glycerin suppositories containing 0.5 per cent zinc sulfate may be gently inserted into the vagina as needed. In cases of acute cervical gonorrhea the use of suppositories, or any intravaginal medication, is usually best omitted.

Sulfonamide compounds have yielded good results and have greatly reduced the time required for the treatment of acute gonorrhea. When these chemotherapeutic agents are employed, adequate facilities should be available for observing the condition of the blood before and during the course of therapy. The patient must be carefully followed by smear and culture methods for evidence of relapse, since the rapidity with which an apparent cure may be obtained often imparts a false sense of security.

Artificial fever therapy also yields a goodly percentage of early cures in cases of acute gonorrhea, but the tendency at present is to reserve this mode of therapy for "sulfanilamide failures."¹

Chronic Stage.—In chronic cervical infections a variety of methods of treatment are available, depending on the degree of the pathologic changes and the familiarity with the various methods.

The aim in treatment is the destruction of the infected glands, the establishment of free drainage and the restoration of the normal anatomic contour and histologic structure of the cervix.

Topical applications of antiseptics and caustics to the cervix are of limited usefulness except when the infection is superficial. Before applying these, the cervical canal and lips are first thoroughly cleansed with sodium bicarbonate solution (25 per cent). If the mucous plug is tenacious, it may be dissolved by the careful application of sodium hydroxide (10 per cent), or it may be coagulated with silver nitrate (10 per cent) and then removed. For painting the diseased area silver nitrate (from 10 to 25 per cent) has long been employed. The excess is removed with saline solution and the vaginal membrane protected with a tampon saturated with boroglycerin. This treatment is repeated once or twice a week until the structure returns to normal.

In the majority of cases the mechanical destruction of the infected area by the actual cautery is far more effective and whenever possible should be used in cases

dependent on endocervical infection. In cases of a superficial nature the broad cautery blade at "dark red heat" should simply sear or char the inflammatory area. With the inflammatory process extending into the deep cervical tissues with involvement and dilatation of the glands (cystic formation), cauterization should be more thorough and the affected glands themselves should be destroyed. The same result may be achieved with Hyams's conization method.

If active infection with a virulent organism is still present, spread of the infection may follow electrocoagulation and cauterization, especially if this is inefficiently done.

In chronic gonococcal infection a course of sulfanilamide therapy preceding cauterization has been recommended.

NONSPECIFIC VAGINITIS

In long-standing cervical infections, the continuous lowering of the vaginal acidity with the profuse alkaline cervical discharge may result in the displacement of the normal vaginal flora, which usually consists of gram-positive lactobacilli (Döderlein's bacilli), by a variety of other organisms. Not infrequently this results in a low grade nonspecific vaginitis. The prolonged use of

PRESCRIPTION 1.—Acid Vaginal Douche

	Gm. or Cc.
R Chlorthymol	1.3
Menthol	2.0
Methyl salicylate	2.0
Lactic acid in sufficient quantity.....to make	180.0

Mix and label: A teaspoon in 2 quarts of hot water, to be used as a vaginal douche morning and evening.

irritating chemical douches, persistent trauma, or long-standing vaginal hypo-acidity may also produce this condition.

The underlying etiologic factor should be determined and corrected. The associated leukorrhea may be controlled and the return of the normal flora hastened by the use of acid vaginal douches (prescription 1) twice daily.

Ordinary vinegar, 1 tablespoon to 2 quarts of water, as recommended by Karnaky,² may also be employed.

PRESCRIPTION 2.—Acid Vaginal Jelly

	Per Cent
R Lactose	6.000
Citric acid	0.275
Tragacanth	1.73
Irish moss	1.75
Glycerin	22.58
Boric acid	2.00
Water	100.00

More recently we have also employed an acid vaginal jelly, adjusted to p_H 4.0 (prescription 2), 5 cc. of which is introduced with a vaginal applicator before retiring.

VAGINAL TRICHOMONIASIS

That trichomonad infection is one of the most common causes of leukorrhea is attested by the observation that a large percentage of gynecologic and obstetric patients encountered in routine practice suffer with this type of infection, which is almost always accompanied by an abnormal vaginal discharge.

1. Jones, Nathaniel; O'Hara, G. P., and Warren, S. L.: Fever Therapy for the Treatment of Gonococcal Infections in "Sulfanilamide Failures," Tr. Am. Neisserian M. Soc., 5th annual meeting, 1939, pp. 150-160.

2. Karnaky, K. J.: Normal Physiologic Douches, South. M. J. 30: 69-70 (Jan.) 1937.

The number, however, seeking treatment for the condition is dependent not simply on the presence of the parasite in the vaginal secretion but also on the social status and personal habits of the individual. The severity of the symptoms is also dependent on the accompanying bacterial invaders.

It must be acknowledged, regretfully, that a specific method of prophylaxis is as yet not forthcoming, since the medium of transmission of the disease is not completely known.

The majority of infections probably occur as the result of contamination with moist vaginal secretion of infected patients.³ It is possible that a small number of patients become infected by sexual contact, since it has been demonstrated that trichomonads are present—usually in small numbers—in the urethra or prostate of from 5 to 10 per cent of men.⁴

Prophylactically, a mild antiseptic douche, immediately following the exposure to contamination, such as bathing in still water pools, contact with contaminated tubs, toilet seats or linens, or sexual congress, may provide a reasonably safe means of protection.

With regard to active treatment, it may be said that almost any local cleansing measure will afford temporary symptomatic relief, but recurrence is almost certain to ensue unless treatment directed to destroy all the flagellates is diligently practiced and continued until the genital tract remains parasite free through at least three or four menstrual periods.

Here it may be pertinent to emphasize that, although trichomonads are easily destroyed by drying and weak antiseptics, a few survivors not reached in the vulvovaginal folds, the urethra or the cervix will rapidly multiply and in the course of from twenty-four to forty-eight hours provoke symptoms of an active nature. Therefore it is not only desirable but essential that the first three or four treatments be administered at daily intervals. These initial treatments must come in contact with every part of the lower genital canal and hence should be conducted by the physician rather than by the patient herself.

Technically, the steps of the local treatment which we carry out may be described as follows:

1. Thorough exposure and cleansing of the cervix, vagina and external genitals are essential. For this purpose, tincture of green soap, diluted twenty times with warm water, or a saturated solution of sodium perborate may be used. The latter has the advantage of effervescing when in contact with the tissues, thus aiding in the cleansing process. On the other hand, burns have occasionally been reported with the use of sodium perborate.

2. Any organisms within the cervical canal are destroyed by carrying an applicator dipped in a strong antiseptic solution, such as tincture of iodine, well into the structure.

3. The entire vaginal tract is thoroughly dried with soft cotton pledgets or with a stream of warm air, following which the speculum may be removed.

4. A nonirritating aqueous antiseptic, such as acriflavine 1:1,000, is introduced into the urethra with a

medicine dropper. The introitus and external genitalia are then thoroughly dried with cotton or warm air.

5. Following the drying process an effective trichomonadicidal agent is applied to the vulvovaginal tract. The use of antiseptic powders in a drying base have been found especially effectual. Powders of this character may be insufflated by a vaginal powder blower.

A fine grade of kaolin is usually employed as a drying base and, in some instances, this alone may overcome the disorder. It is usually necessary to combine the kaolin with a protozoacide. The pentavalent arsenicals, such as acetarsonic and carbarsone, are frequently used. Sodium bicarbonate may be added to these preparations to increase their solubility (prescription 3).

PREScription 3.—Vaginal Powder with Protozoacide

R	Acetarsonic or carbarsone.....	1 part
	Sodium bicarbonate	1 part
	Kaolin	to make 6 parts
Mix and label: 5 Gm. to be insufflated into the vagina by the physician.		

Silver picrate, 1 per cent, in kaolin is also highly recommended.

A less expensive powder, which we have found useful, is given in prescription 4.

PREScription 4.—Vaginal Powder with Zinc Sulfate

		Gm.
R	Zinc sulfate	0.5
	Boric acid	50.0
	Kaolin	to make 100.0
Mix and label: 5 Gm. to be insufflated into the vagina by the physician.		

The addition of lactose to these powders has been recommended by some workers to aid in the reestablishment of a normal flora of Döderlein's bacilli.

6. The foregoing treatment should be repeated daily for three successive days and then at intervals of three days until at least six treatments have been given.

7. Following the three initial treatments it is advantageous to have the patient employ a cleansing acid douche (prescription 1). From 2 to 4 quarts of the solution at 105 F. should be used.

8. It is often necessary to continue daily vaginal douches during the menstrual period, since, as is well known, many recurrences follow immediately or shortly after menstruation.

9. Vaginal suppositories medicated with various trichomonadicides are frequently used, but as a rule they simply control rather than overcome the infection. They are recommended as therapeutic adjuvants but not as curative agents.

10. The marital relation should not be practiced during the course of active therapy. Recurrence following coition calls for an examination of the husband to determine whether he is or is not harboring the parasite in the urethra or prostate.

11. After an initial course of treatment all local measures may be discontinued for several days, and the vaginal secretion during this time should be examined for the presence of trichomonads. No patient should be considered cured until she has passed through three or four menstrual periods wholly free from the organisms.

12. In resistant cases it is often necessary to treat the patient every second or third day through two or

3. Bland, P. B., and Rakoff, A. E.: The Incidence of Trichomonads in the Vagina, Mouth and Rectum; Evidence that Vaginal Trichomonads Do Not Originate in Mouth or Intestine, *J. A. M. A.* **108**:2013-2016 (June 12) 1937.

4. Riba, L. W.: Trichomonas Urethritis, *J. A. M. A.* **96**:2100-2102 (June 6) 1931. Ackermann, Armin: Die Trichomonas vaginalis Infektion, *Dermat. Ztschr.* **71**:132-157 (May) 1935. Bland, P. B., and Rakoff, A. E.: Trichomonas Vaginitis, in *Cyclopedia of Medicine*, Philadelphia, F. A. Davis Company, vol. 13, 1937.

three menstrual cycles. In such instances one must carefully guard against cumulative toxic effects from the prolonged use of arsenicals, silver salts, picrates and the like. It is sometimes advisable to alternate treatment with several trichomonadicidal agents.

13. In pregnancy active treatment may be indicated because of the severity of the symptoms or the "unhealthy" character of the vaginal secretion. In such instances it is best to begin treatment as early as possible, and under no circumstances should intravaginal treatment be continued beyond the thirty-sixth week of gestation.

Local treatment should be given with the utmost gentleness. The powder is insufflated without appreciably increasing the intravaginal pressure. The number of douches are reduced to a minimum and are given at very low pressure, without a nozzle.

MONILIASIS

The increase in glycogen and vaginal acidity which occurs during gestation favors the growth of *Monilia* and related yeastlike fungi. Vaginal moniliasis is therefore found far more commonly in pregnant women, in whom it is associated with thick, white, "cheesy" thrush patches encrusted on the vaginal walls and accompanied by considerable inflammation and edema of the vulva with marked pruritus.

In the treatment of moniliasis three objectives should be kept in view: first, prompt relief of the intense pruritus; second, destruction of the causative organisms, and, third, prevention of the spread of the infection to other surfaces, such as the surrounding glabrous skin or nipples or to the newborn, in whom it may cause oral thrush by contamination at the time of delivery.⁵

These objectives may be obtained by first swabbing the entire lower genital tract and vaginal canal every second day with sodium bicarbonate (5 per cent) until all secretions and thrush patches are removed and then thoroughly painting the structures mentioned with an aqueous solution of gentian violet or a solution of gentian violet plus acriflavine (prescription 5).

PRESCRIPTION 5.—Solution of Gentian Violet and Acriflavine

℞ Gentian violet, 1 per cent aqueous solution.....	1 part
Acriflavine, 0.1 per cent aqueous solution.....	1 part

Mix and label: Apply locally.

This solution does not stain as intensely and appears to be equally effective.

The solution is dried with a current of air from a hair drier or Sorenson pump while the speculum is still in situ. Although the relief afforded by the application of these solutions is prompt, they are objectionable to some patients because of staining of the bed linen and wearing apparel as they drain from the vaginal canal.

While gentian violet inhibits the growth of *Monilia*, its actual killing power is low. For this reason Hessel-tine⁶ and other observers advocate the use of some form of iodine as a more potent fungicide.

5. Hessel-tine, H. C.; Borts, I. C., and Plass, E. D.: Pathogenicity of the *Monilia* (Castellani), Vaginitis and Oral Thrush, *Am. J. Obst. & Gynec.* 27:112-116 (Jan.) 1934. Bland, P. B.; Rakoff, A. E., and Pincus, I. J.: Experimental Vaginal and Cutaneous Moniliasis, *Arch. Dermat. & Syph.* 36:760-780 (Oct.) 1937.
6. Hessel-tine, H. C.: Experimental and Clinical Therapy of Vulvo-vaginal Mycoses, *Am. J. Obst. & Gynec.* 34:439 (Sept.) 1937.

Compound solution of iodine, diluted from five to ten times with water, may be used to paint these structures instead of aniline dyes, though it is worthy of mention that symptomatic relief will not be so promptly provided.

Starting twenty-four hours after the topical application is made by the physician, the patient is instructed to use an alkaline douche (prescription 6) morning and evening.

If the vulvar skin has become infected with the fungus, more persistent treatment is necessary. In

PRESCRIPTION 6.—Alkaline Douche

	Gm.
℞ Zinc sulfate	12.0
Menthol	2.0
Camphor	2.0
Sodium bicarbonate	90.0
Sodium borate	90.0

Mix and label: A teaspoon in 2 parts of warm water to be used as a douche on retiring.

addition to treating the vaginal infection, the cutaneous lesions must be diligently cared for by the application of gentian violet in alcoholic solution (5 per cent) or tincture of iodine (2 per cent).

PRESCRIPTION 7.—Fungicidal Ointment

	Gm.
℞ Ammoniated mercury	1.6
Salicylic acid	2.0
Wool fat	12.0
Petrolatum	to make 60.0

Mix and label: To be applied to the parts affected two or three times daily.

Fungicidal ointments, as recommended by Wise and Wolf,⁷ are useful in resistant cases (prescription 7).

FUSOSPIRILLOSIS AND RELATED INFECTIONS

Vaginal infections due to Vincent's organisms or various types of *Spirillum* and *Spirochaeta* are usually associated with and favored by uncleanliness. They may result from abnormal sexual practices or from autoinoculation from the mouth of women suffering with infection of the "gums." As a secondary infection it may become superimposed on other ulcerative lesions, especially those of a granulomatous character.

In cases of fusospirillosis the discharge is profuse, thick, yellow and purulent. The morbid changes in the vaginal mucosa may be pronounced. The membrane is injected and raw and presents a "raw beef" appearance. In some instances rather deep ulcerations may occur.

An infection clinically identical and probably acquired in the same way may be caused by other types of *Spirillum* and *Spirochaeta*⁸ of low grade pathogenicity such as are frequently found in the mouth. The organisms may be demonstrated by dark field examination or in smears stained with Giemsa's spirochetal stain.

Treatment.—These infections usually respond rapidly to simple local cleansing measures unless there is another underlying cause present. An effective means of therapy is as follows:

1. The entire lower genital tract is thoroughly swabbed with a saturated solution of sodium perborate,

7. Wise, Fred, and Wolf, Jack: The Pharmacopeia and The Physician: Use of Dermal Parasitocides, *J. A. M. A.* 107:1126-1132 (Oct. 3) 1936.

8. Allen, E. A.: Diagnosis and Treatment of Persistent Vaginal Discharge, *M. Clin. North America* 21:307-318 (Jan.) 1937.

which should be employed with care, since it occasionally may lead to burns of the mucous membrane.

2. An arsenical drying powder, such as that described in the treatment of trichomonas vaginitis, is insufflated into the vagina. This is repeated two or three times a week.

3. The patient is instructed to use the vaginal douche given in prescription 8 twice daily.

PRESCRIPTION 8.—Methyl Salicylate and Sodium Perborate Douche

	Gm.
R Methyl salicylate	2.0
Sodium perborate	120.0
Mix and label: Two teaspoons in 2 quarts of warm water to be used as a vaginal douche morning and evening.	

The thorough and frequent daily application of neosarsphenamine, 10 per cent, in glycerin to the entire genital tract is also very effective.

LEUKORRHEA IN CHILDREN

Because of the delicate nature of the epithelial lining of the vagina, together with the neutral or alkaline reaction of its secretion, the canal itself in little girls is especially susceptible to bacterial invasion.

Infections of the vagina may be due to a specific pathogen, particularly the gonococcus, or they may be "nonspecific," caused by a variety of organisms. The introduction of foreign bodies into the vagina frequently gives rise to the latter type of infection.

Treatment.—The first essential in the treatment of gonorrheal vaginitis in children is, of course, strict isolation in order to prevent contamination of the other children in the household or institution.

Numerous therapeutic measures have been recommended and practiced in the treatment of this type of infection, though until recently none were really wholly dependable or satisfactory.

The methods one may employ may be thus enumerated:

1. Local Application of Antiseptics: Antiseptics may be effectively introduced into the vagina in the form of a water-soluble jelly. The formula suggested by Reichert⁹ has proved very satisfactory: "To 2 drachms [8 Gm.] of tragacanth ribbon is added 8 ounces [240 cc.] of an aqueous solution of the antiseptic to be used and 4 grains [0.26 Gm.] of sodium benzoate. The mixture is allowed to swell and is then expressed through cloth." Silver nitrate (from 0.5 to 1 per cent), strong protein silver (2 per cent) and various other antiseptics may be used for this purpose.

The jelly is warmed to body temperature before use and from 5 to 10 cc. is introduced into the vagina through a soft rubber catheter attached to a 10 cc. syringe.

A small, snugly fitting pad is applied and the child kept in the dorsal position for ten minutes to permit the jelly to harden.

Treatment should be repeated every two to three days and, in resistant cases, daily.

Although with persistent treatment good results may be obtained in many cases with this form of treatment, the results are not as good, as regards either prompt-

ness of cure or percentage of relapses, as are obtained with estrogen suppositories.

2. Estrogenic Hormones: Treatment with estrogens, first suggested by Lewis,¹⁰ is now accepted as a notable advance in the treatment of gonococcal vulvovaginitis.

Although the hormone may be effectively administered in a number of forms, the use of suppositories has proved to be the most convenient route and is accompanied by fewer undesirable estrogenic effects.

A satisfactory technic which may be employed is as follows:

(a) The mother of the child is instructed simply to cleanse the vulva with soap and water.

(b) A small vaginal suppository, containing from 500 to 1,000 international units of an estrogenic hormone is gently introduced into the vaginal canal at bedtime. In the majority of instances the mother may be taught to do this.

In from four to ten days a favorable response is generally noted in the vaginal smears, since large squamous epithelial cells replace the leukocytes and smaller cells as cornification occurs. The vaginal secretion becomes white and flaky and markedly acid in reaction. In this environment the gonococcus disappears.

It is generally necessary to continue treatment for four weeks, and when the response is not so prompt this may be extended to six weeks.

Repeated negative smears at weekly intervals for a period of from three to four months after treatment has been discontinued are necessary before the child can be considered cured.

If evidence of other estrogenic effects are noted, such as enlargement of the breasts, uterine bleeding, hypertrophy of the labia and growth of pubic hair, the hormone should be withdrawn and replaced with another form of treatment.

In resistant cases, or in cases in which repeated relapses occur, the cervix should be inspected with a vaginoscope or cystoscope for evidence of infection, and smears and cultures taken from this structure. The rectum should also be examined for evidence of infection. There is considerable difference of opinion as to how frequently these structures serve as foci of reinfection.

Exceptionally good results are obtained in the treatment of "nonspecific" infection with estrogen therapy. Care must be observed, however, to eliminate first the presence of an underlying factor, especially the removal of any foreign bodies.

3. Sulfanilamide: Further investigation is required before the place of sulfanilamide and its related compounds can be established in the treatment of gonococcal vulvovaginitis.

In properly chosen cases, treatment of gonococcal vulvovaginitis with sulfanilamide has given fairly good results. It is not to be recommended as a routine procedure and is perhaps most judiciously employed when other methods of treatment fail.

The treatment of gonococcal vulvovaginitis with sulfanilamide necessitates hospitalization, since careful observation, including blood counts and blood sulfanilamide levels, are of the utmost importance.

The dosage that should be employed has not yet been established to the satisfaction of all workers. A dose of three-fourths grain (0.05 Gm.) per pound

9. Reichert, J. L.; Epstein, I. M.; Jung, Ruth, and Colwell, Charlotte A.: Infection of the Lower Part of Genital Tract in Girls, *Am. J. Dis. Child.* 54: 459-495 (Sept.) 1937.

10. Lewis, R. M.: A Study of the Effects of Theelin on Gonorrheal Vaginitis in Children, *Am. J. Obst. & Gynec.* 26: 593-599 (Oct.) 1933.

(450 Gm.) of body weight is frequently recommended at the onset. This may be given in four divided doses with an equal amount of sodium bicarbonate for the first two days. The dose may then be reduced to one-half grain (0.032 Gm.) per pound of body weight for from two to three weeks, depending on the rapidity with which the smears become negative.

Smears must be rechecked at frequent intervals.

As Schaffner and his associates¹¹ and Benson¹² have pointed out in the reviews of the subject, the percentage of cures obtained by different workers has varied greatly. This has been attributed in part to ineffective dosage, although Benson states that there appears to be little relation between the amount of sulfanilamide given and the result of treatment.

LEUKORRHEA OF ENDOCRINE ORIGIN

Hyperestrogenism.—In newborn infants there is frequently present a profuse, white and flaky discharge which persists from several days to two weeks. This results from the desquamation of the vaginal epithelium, which has been overstimulated by the high blood estrogen obtained through the maternal circulation.

The moderate increase in vaginal discharge which is a physiologic accompaniment of pregnancy may be attributed to the same cause.

A similar type of noninfective leukorrhea is sometimes seen in nonpregnant women, especially young women.¹³ This is usually worse in the latter half of the menstrual cycle and is subject to periods of remission and exacerbation. Pruritus is frequently an accompanying symptom.

The discharge resembles the normal secretion in character and is highly acid (usually p_H 3.9 to 4.2). Stained smears usually reveal large cornified epithelial cells and the vaginal bacilli of Döderlein.

This type of leukorrhea is exceedingly difficult to treat. Progesterone from 2 to 5 mg. two times a week in the last two weeks of the cycle sometimes yields good results, while in other instances it may have little or no beneficial effect. An alkaline antipruritic douche (prescription 6) is of palliative value.

A similar type of discharge may develop during the period in which large doses of estrogens are being administered for other purposes.

Hypo-Estrogenism.—Atrophic changes in the vaginal epithelium are frequently seen in the postmenopausal period. Nonspecific infection with a variety of organisms often occurs and results in a purulent discharge. Pruritus is also a prominent symptom. If untreated, ulcerations and adhesions of the vaginal membranes may result.

For this condition estrogen is a specific therapeutic agent. This may be given parenterally or, preferably, in the form of large vaginal suppositories. In the beginning, one suppository, containing from 2,000 to 10,000 international units of estrone or estradiol, may be inserted nightly. After vaginal cornification occurs this is reduced to the minimum amount that will afford relief of symptoms and maintain the vaginal membrane in a healthy state.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

WESTINGHOUSE SUNLAMP MODEL NO. ES2404 ACCEPTABLE

Manufacturer: Westinghouse Electric and Manufacturing Company, Bloomfield, N. J.

The Westinghouse Sunlamp, Model No. ES2404, containing an S-4 type lamp, provides ultraviolet radiation of an intensity and spectral distribution rendering it suitable for unsupervised use by the layman. The ultraviolet source is mounted in a reflector on an adjustable support.

Type S-4 Mazda Sunlamp bulb consists of an electric arc discharge through mercury vapor, between activated metal electrodes sealed in a small quartz capillary tube, which in turn is enclosed in a bulb of special glass and is opaque to ultraviolet radiation of short wavelengths.

Radiation passing through the quartz capillary tube is essentially that of the so-called "hot quartz" mercury arc. However, by enclosing the quartz lamp in a bulb of glass of a composition and thickness to absorb completely the intense emission lines of wavelengths shorter than about 2,800 angstroms, there remains a series of strong emission lines at 2,894, 2,967, 3,024 and 3,132 angstroms (and longer wavelengths) favorably situated in the spectral band of ultraviolet in sunlight recognized as having a specific therapeutic effect.

The S-4 Lamp is operated on the ordinary (115 volts) house lighting (alternating current) circuit but it requires an intermediary, especially designed, transformer to maintain the proper voltage and operating temperature. The approximate power used is 100 watts. In the lamps tested, on 115 volts input, the current through the lamp ranged from 2.1 to 2.3 amperes.

In order to determine whether the Type S-4 lamp complies with the Council's requirements of acceptability as a sun lamp, in addition to the data submitted by the manufacturer, spectral ultraviolet radiation measurements were made in a laboratory selected by the Council. These measurements fully confirmed the data submitted by the manufacturer showing that the radiation of wavelengths shorter than 2,800 angstroms is immeasurably small and hence these lamps qualify as sun lamps so far as spectral quality (wavelength) of radiation is concerned.

In this investigation the lamp was placed close in front of the quartz-fluorite achromatic spectroradiometer and the spectral

Spectral Intensities

Wavelength (Angstroms)	Relative Energy (Average of 3 Lamps)
3,132	7.96
3,024	2.59
2,967	1.15
2,894	0.28
2,804	0.09
Total 12.07	

intensities were measured with a vacuum thermopile. The relative spectral intensities (galvanometer deflections) corrected for absorption in the spectroradiometer are given in the accompanying table.

The radiation at 2,804 angstroms (and shorter if measurable) is about 0.75 per cent of the total of all wavelengths, including 3,132 angstroms and shorter. Mounted in an aluminum reflector the radiation at 2,804 angstroms and shorter, relative to the total, would be still lower. Hence these lamps comply with the Council's requirements for acceptability of a sun lamp for spectral quality of ultraviolet radiation.

Erythema Test: The untanned inner upper arm, at a distance of 24 inches (61 cm.) from the lamp in an aluminum reflector,

was exposed to lamp number 12 on 108 volts for intervals of two, four, six, eight, ten, twelve and fifteen minutes. A mild erythema was obtained on six minutes' exposure. The exposures of eight minutes and longer were too long—still red after three days. With a standard voltage (115 volts) and a modern reflector the exposure time for a minimum perceptible erythema would be still shorter.

The Council on Physical Therapy voted to accept the Westinghouse S-4 Sunlamp for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
PRELIMINARY REPORT. PAUL NICHOLAS LEECH, Secretary.

PRELIMINARY REPORT ON HISTAMINASE: TORANTIL

According to reports in the literature, Torantil, an extract of intestinal mucosa of standardized histamine detoxifying potency marketed by Bayer (I. G. Farbenindustrie A. G.) for the treatment of allergic conditions and intestinal intoxications, was introduced into this country by the Winthrop Chemical Company as a brand of histaminase. The latter now markets a similar product under the same name but formerly used the provisional designation "T 360," under which identification it has been supplied to investigators in ampule form for experimental use. The concern markets the product in tablets of 5 units each, under the original name Torantil. In this form the preparation was submitted to the Council at its request.

The firm promotes Torantil as an "Antiallergic (Histamine-Deoxidizing)" agent of the following description:

Extract from the mucosa of the small intestines and desiccated kidneys of hogs, containing a histamine destroying enzyme, histaminase, in an active and stable form. Biologically standardized in histamine detoxicating units, one unit being the amount which will inactivate one milligram of histamine hydrochloride during incubation at 37.5 C. for twenty-four hours. Possesses all the known properties of histaminase.

The indications for Torantil are stated as follows:

For use in the prophylaxis and treatment of allergic disorders, including asthma, hay fever (vasomotor rhinitis), urticaria, gastrointestinal disturbances, serum sickness, angioneurotic edema, atopic dermatitis, eczema, hypersensitivity to insulin, drugs and physical agents, such as cold, heat and light. Also employed in acne vulgaris.

The average initial dose of Torantil recommended by the manufacturer is from 10 to 15 units orally three times a day before meals, gradually increased to from 20 to 25 units in severe cases or decreased to a maintenance dose of from 10 to 20 units daily after clinical symptoms are controlled. Warning of possible unfavorable reaction from the use of the preparation in persons hypersensitive to hog protein is included in the firm's advertising. The firm distributes a descriptive card, "Torantil" (from which the quotations were made), three leaflets, "After Four Years of Persistent Investigations," "For Diseases of Allergy" and "Clinical Application of a New Concept of Allergy," three folders, "Effective Control of Many Allergies," "Physiologic Basis for a New Treatment of Allergy" and "Histaminase Treatment of Allergy," and a booklet, "Torantil," accompanied by a clip-sheet, "Silver Jubilee of an Interesting Discovery." The last named piece refers to the discovery twenty-five years ago by Eustis¹ that lethal doses of histamine for guinea pigs can be inactivated by incubation with the liver pulp of the turkey buzzard at 38 C. for twenty-four hours. He believed this action to be due to some enzyme, since boiling temperature resulted in inhibition of the inactivating substance.

LITERATURE

In 1930 Best and McHenry² showed that simple saline extracts of various animal organs when used fresh and untreated had the property of destroying the histamine in a

solution to which they were added. They found that almost every tissue contains a histamine-inactivating substance for which they proposed the name histaminase, because of properties characteristic of enzymes. By perfusion experiments they were able to demonstrate in the dog that the kidney and the intestine are the richest sources of histaminase. They reported a method of extraction and assay and suggested: "A convenient unit of histaminase would be the activity necessary to destroy 1 mg. of histamine during twenty-four hours' incubation at 37 C., in a phosphate buffer solution at pH 7." The authors found that the change produced in histamine during inactivation appears to be oxidative, since it is inhibited by potassium cyanide under anaerobic conditions and is accelerated by oxygen. They also found that reduction of the iminazole value parallels the degree of inactivation of histamine and suggested that rupture of the iminazole nucleus occurs in the histamine or that a complex nondialyzable compound is produced. The authors conclude as follows: "Since it has not been established that histamine is the causative agent in any pathological condition there would be no obvious clinical application of histaminase, even if it should be established that the ability of an organism to inactivate histamine can be increased by administration of the enzyme."

The firm submits thirty-six references to reports in the literature, in addition to the one just reviewed, in support of its claims that histaminase is of prophylactic and therapeutic value in a variety of allergic manifestations. A review of these and other recent reports in the literature indicates the importance of the concluding statement of Best and McHenry, just quoted. Thus far reports do not definitely establish histamine as the exciting cause of any disease. Although there is some evidence that histamine produces effects similar to the reactions which occur in certain allergic states, the theory that it is the common denominator through which a variety of exciting causes can produce asthma has not been established. Evidence that histamine, the so-called effector set free by cellular injury, may be liberated by many different agents is accumulating, but there is no conclusive evidence to prove that an excess is invariably associated with various allergic manifestations. Difficulty has been encountered because of the small amount of histamine present in the blood of patients with asthma, which until recently could be detected only by cumbersome biologic methods. There has also been difficulty in determining the mechanism by which the organism may dispose of an excess of histamine.

The presence of a protective enzyme, histaminase, in nearly all tissues of most species has been confirmed by several investigators. While most species reveal the greatest quantities in the kidney, the absence of histaminase in the kidney of the rat has also been reported. Small amounts of histamine administered slowly by vein produce none of the effects usually observed, suggesting that the blood is able to inactivate small quantities gradually. This has been shown to be due not to histaminase but rather to the red cells which take up histamine and thus prevent its physiologic activity. Rose and Browne³ have studied the question of what happens to histamine in rats when it is rapidly injected intravenously in both large and small doses. They first confirmed other reports that histamine disappears rapidly from the blood. In the rat they find that histaminase occurs only in the lung and small intestine, but within fifteen minutes after intravenous injection of histamine the tissues contain more histamine than the blood. After this time the rapidity of disappearance from the tissues occurs in the following order: blood, lung, lymph gland, liver and kidney. After thirty minutes the rate of disappearance is greater from the kidney than from the other tissues named. The authors hypothesize that, since the kidney of the rat contains no histaminase, the difference in the rate of disappearance of histamine may be due either to a transfer of histamine from other tissues to the kidney, which then destroys it gradually by another mechanism unable to gain headway with the continuous transfer until after thirty minutes, or to the slow liberation of transferred histamine from the kidney to the

2. Best, C. H., and McHenry, E. W.: *The Inactivation of Histamine*, *J. Physiol.* 70: 349 (Dec.) 1930.

3. Rose, Bram, and Browne, J. S. L.: *The Distribution and Rate of Disappearance of Intravenously Injected Histamine in the Rat*, *Am. J. Physiol.* 124: 412 (Nov.) 1938.

histaminase-containing tissues, where it is inactivated. It has been shown that histamine is not excreted in the urine of the rat within three hours after injection. Experiments of the authors show that adrenalectomy markedly retards the rate of disappearance of histamine from the tissues, especially the kidney. The essential importance of the study is to suggest that factors other than histaminase may defend the organism against the action of histamine.

Attempts to demonstrate the importance of histamine inactivation in combating symptoms of various allergic states have been made by a few investigators whose reports of results of treatment with histaminase may be found in the literature. Recently Karady and Browne⁴ demonstrated that histamine and anaphylactic shock were effectively prevented by parenteral preadministration of histaminase in guinea pigs given large doses of histamine or egg white after previous sensitization with this protein. Of the ten animals in each of the two untreated control groups given histamine and egg white, only seven and four given histamine and egg white respectively died. These control results further support the belief that a physiologic mechanism other than histaminase may be effective in combating an excess of histamine. Foshay and Hagebusch⁵ report the symptomatic relief of serum sickness in twenty of twenty-two patients treated with oral and intramuscular histaminase. Both these reports are based on the use of Torantil furnished by the firm.

Prickman,⁶ in the discussion of Serum Sickness: Effective Treatment and Probable Prophylaxis by Means of Histaminase, reviewed by Dr. Lee Foshay at the eleventh annual meeting (Chicago, Nov. 4 and 5, 1938) of the Central Society for Clinical Research, reported relief in only 34 per cent of twenty-six cases of vasomotor rhinitis treated orally with histaminase. He indicated that the results reflect an apparent variability in the potency of the preparation and finds a limit to the tolerance for it in one case due to food sensitivity. Distressing abdominal cramps were produced when the dose was increased beyond a certain limit. In the same discussion, Roth⁷ confirmed Dr. Prickman's observation of the variability of the potency of the material in her review of continued good results from its oral use in patients hypersensitive to cold and insulin. Foshay⁸ pointed to the probability that the product is a mixed substance and that others also have reported variance of potency in different batches of the material. He indicated that his studies were based on cases treated from a single batch of the material and that less prompt relief of symptoms is obtained by the use of enteric-coated tablets than when the preparation is administered intramuscularly.

Roth and Rynearson⁷ report further varying results with the oral use of Torantil in the treatment of prolonged local cutaneous reactions due to insulin sensitivity. Some of the failures in the twelve cases reported were attributed to a decreased potency of the particular batch of material used in the study. Laymon and Cumming⁹ administered histaminase orally and intramuscularly for from four days to three weeks in the treatment of seventeen cases of urticaria and obtained ten cures and two improvements. The average time for a cure was 10.7 days. Of the cases of atopic dermatitis treated, none were improved. Rackemann¹⁰ summarizes briefly the recent literature on allergy and, with reference to its relation to histamine, aptly indicates the present uncertain state of knowledge concerning histamine and so-called histaminase. Miller and Piness¹⁰ report the failure of histaminase to give unequivocal evidence that this enzyme was responsible for the relief or prevention of any of the signs or symptoms in forty-

two allergic patients treated with Torantil supplied by the firm under the experimental name T 360.

[Since the foregoing report was set in type, several additional papers have appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION as follows: Among them is one by Keeney (114:2448 [June 22] 1940), in which oral administration of histaminase failed to give relief. Another article by Corper and Cohn reports that histaminase of pre-determined in vitro strength did not appreciably retard intoxication (general or cutaneous hypersensitivity) produced by an intoxicating injection of the specific tuberculo-protein in guinea pigs previously sensitized to the protein. Best and McHenry of the University of Toronto, in the correspondence note to the editor (115:235 [July 20] 1940), point out that neither their original report, nor in any subsequent publication by them, has it been suggested that the administration of histaminase might be a useful mode of therapy. They indicate that they have been unable to confirm the results of Karady and Browne in the protection of guinea pigs against anaphylactic and histamine shock with histaminase. The article by Goldberg, to which reference was made in this report, has also been published (115:429 [Aug. 10] 1940).—ED.]

LETTERS FROM PHYSICIANS

Several letters from physicians written at the request of the Winthrop Chemical Company contain statements (mostly opinions) favorable to the use of Torantil in allergic conditions. Grafton T. Brown of Washington, D. C., reports the oral use of Torantil in fifty or more cases comprising urticaria, asthma, perennial hay fever, eczema, migraine and other allergic manifestations. He reports the use of the product, injectable form, in one case of migraine without benefit. Briefly he gives his impressions on the oral use. He seldom notes toxic manifestations; possibly two patients may have had bad effects from the preparation. This would seem doubtful as they were very nervous and complained about a great variety of drugs when administered. He reports no benefit in cases of bronchial asthma, vasomotor rhinitis, pruritic dermatitis or migraine. Some of the cases of urticaria and angioneurotic edema were benefited. He reports encouraging results in physical allergy (heat and cold).

Robert L. Nelson, Duluth, Minn., tells of observations he reported before the St. Louis Medical Society. He states that he obtained complete relief in mild hay fever of ragweed types. Severe types were completely controlled when the pollen count was low but received no benefit when the patients went into an area where the pollen concentration was high. Two of his ragweed cases were complicated by asthma during the hay fever attacks and apparently were much benefited by the drug. The effect of the drug wore off in thirty-six hours. It is interesting to note that he reports one case sensitive to pork which was refractory because of the pork origin of the product. This is hard to understand if histaminase is the key to the cure of allergy. He further reports several cases of "cold in the head" in which there was complete relief.

A letter from Dr. C. M. Charles of St. Louis includes excerpts from a manuscript in preparation. His experience has been that many cases require high daily doses for control, as much as 150 units, which would be thirty tablets. Treatment in several of his cases with migraine was complicated by the use of other drugs, ergotamine tartrate and ephedrine. Some of the cases lead to certain doubts, since the migraine disappeared not to return for several weeks after administration of Torantil was stopped. He reports cases of bronchial asthma that were benefited but the follow-ups on these cases are too short to afford a basis for final conclusions. Vasomotor rhinitis, mostly ragweed hay fever cases, seem to have been benefited mostly on the larger doses. However, there is considerable variability in the benefits.

Dr. R. O. Muether of St. Louis University School of Medicine reports treating ten cases of rheumatoid arthritis, fifteen cases of primary dysmenorrhea, three cases of asthma, two cases of idiopathic migraine, three cases of menstrual migraine, two cases of urticaria and three cases of allergic rhinitis. While not definitely stated, the letter implies favorable results when adequate doses are employed in the treatment of these conditions. Patients with rheumatoid arthritis were not "markedly improved" but when "swelling was present this was often relieved." Eight of the ten thought they were less stiff and had less pain. Eleven of the fifteen cases of primary dysmenorrhea were benefited in from three to six menstrual periods. "In several instances when the drug was stopped the difficulty recurred only to disappear when the drug was resumed."

Dr. Omer E. Hagebusch, St. Louis, reports the use of Torantil in fifty-five cases of serum sickness including all grades of severity some of "almost fatal type"! "In all but three cases

there has been a very prompt and gratifying relief of symptoms." Thirty-five patients with undulant fever or tularemia who were to receive serum received the product. "When the dose was adequate we could almost always prevent the occurrence of serum sickness." And those developing serum sickness had mild attacks. No toxic effects were noted even though forty tablets a day for five days were given to an occasional patient. Dr. Patrick Nagle, Oklahoma City, telling of his experience, writes "Therapeutic response in some cases has been quite encouraging, in many cases has been discouraging" and feels that "no final word may be passed upon the product at this time."

Dr. Ben A. Newman of Los Angeles writes: "My experience with the use of histaminase has been limited to a relatively small group of patients, but well controlled. All the patients upon whom the drug was used had previously been treated with all the known orthodox measures without effect; and during the period of histaminase exhibition all other active therapy was withheld. Only two dermatoses were studied, neurodermatitis and chronic urticaria. Acute urticarias were not included in my series since I felt the evaluation of therapy would be impossible." He reports no effect in six cases of generalized neurodermatitis (atopic eczema) and four cases of localized neurodermatitis (lichen simplex chronicus). Of five patients with giant urticaria and angioneurotic edema one was not benefited; three were completely relieved with the exception of small evanescent urticarial lesions, permitting gradual reduction of the dose and eventual withdrawal, and one was markedly relieved while taking large doses (from fifteen to eighteen tablets daily) but relapsed when the drug was discontinued. The identity of the orthodox control measures employed as initial treatment is not stated.

(The foregoing communications are those which were received up to May 1, 1940. Similar letters continue to be received, but thus far these offer no evidence of further significance.)

Three manuscripts are submitted by the firm. One, by Ray Williams, H. L. Alexander and T. Kirchner of St. Louis on "The Action of Histaminase on the Histamine Content of the Blood of Rabbits," is a good report of experimental work but has little bearing on the value of Torantil in the treatment of allergic states in human beings. A second paper, by Grace M. Roth and Bayard T. Horton of the Mayo Clinic, on "Histaminase: Physiologic Effects on Man and Its Therapeutic Value in Medicine," was presented at the New York Academy of Medicine before the Section on Medicine, April 16. Slides were used in presentation and no tables or protocols accompany the paper. These authors report ten cases of hypersensitiveness to cold in which following the administration of histaminase for several days only slight systemic or local reaction occurred following immersion of the hand in water at 10 C. for seven minutes. In a few no reaction occurred. All patients previous to the ingestion of histaminase had marked reaction following the procedure. Instances of determination of the gastric acidity before and after the administration of histaminase are described. Marked decrease in the gastric acidity followed the ingestion of the product. "Erythromelalgia of the head," a new syndrome described by Horton (one of the authors) a year ago, yields to histaminase. "We feel that not only is 'desensitization' with histaminase a specific treatment for 'erythromelalgia of the head,' but our recent observations with the use of histaminase leads us to believe that it is almost as effective as 'desensitization with histamine.'" Of seventeen patients with serum sickness, relief in fourteen within eighteen to thirty-six hours was observed. There was no relief in three. When histaminase was started simultaneously with serum in thirteen patients, no serum sickness occurred in eight, only transient urticaria appeared in three and no relief in two. From 45 to 60 units of histaminase administered orally each day to twelve patients with insulin allergy relieved ten. The authors report that eighteen patients with vasomotor rhinitis were relieved of nasal obstruction, watery discharge and sneezing, with definite improvement in the appearance of the nasal membrane, eight patients were benefited, and fourteen patients expressed no relief. These observers have used histaminase in 150 patients without untoward effects. The third manuscript is by Alexander Altose, on "The Treatment of Certain Allergic Skin Conditions with Histaminase," read before the King County

Medical Society, Seattle, in March of this year. Torantil was supplied by the firm. The author reports the results of treatment of eighteen subjects with urticaria, angioneurotic edema and allergic dermatitis: eight greatly improved, six moderately improved and four unimproved.

SUMMARY

The use of histaminase in allergic manifestations was suggested because of the hypothetic histamine-like substance which may be responsible for all allergic responses. In the opinion of the Council this use of histaminase in the treatment of allergic states, although perhaps ingenious and suggestive, has no well established scientific clinical basis. In attempting to evaluate the clinical evidence the Council is confronted with conflicting data. Some physicians report success in one condition and others a lack of it, although enthusiasm is expressed in most of the reports available. What is lacking is a thoroughgoing study over a sufficient period (most of the case reports have been collected during the past year), alternating placebos with the histaminase to see if the effect is real or fanciful. In some of the reports, lack of success is attributed to low potency, though the firm now assures the Council that it has worked out the problems of uniform potency. The unpredictability and variability of allergic phenomena causes the Council to pursue a conservative course toward the efficacy of histaminase in the treatment of these conditions. In any event the name Torantil is meaningless and is not acceptable. The Council does not wish to discourage further experimental investigation of histaminase under rigidly controlled conditions.

The Council voted that, as a brand of histaminase, Torantil lacks evidence to justify its present inclusion in N. N. R.; further, that it is marketed under an objectionable name with claims which are not justified. The Council decided to hold in abeyance further consideration of histaminase and of Torantil until the development of further evidence and authorized publication of the foregoing preliminary report.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LFECH, Secretary.

AMINOPHYLLINE (See New and Nonofficial Remedies, 1940, p. 555).

Aminophylline-Merrell.—A brand of aminophylline-N. N. R.

Manufactured by the Wm. S. Merrell Co., Cincinnati, Ohio. No U. S. patent or trademark.

Ampul Solution Aminophylline-Merrell, 0.48 Gm. (7½ grains), 2 cc.

Ampul Solution Aminophylline-Merrell, 0.24 Gm. (3¾ grains), 10 cc.

ASCORBIC ACID-SQUIBB—(See New and Nonofficial Remedies, 1940, p. 532).

The following dosage form has been accepted:

Tablets Ascorbic Acid-Squibb, 100 mg.: Each tablet is equivalent to 2,000 international units of vitamin C.

SODIUM CACODYLATE (See New and Nonofficial Remedies, 1940, p. 109).

Endo Products, Inc., Richmond Hill, New York.

Ampoules Sodium Cacodylate-Endo, 0.065 Gm. (1 grain), 1 cc.: Benzyl alcohol 1 per cent is added for its local anesthetic effect.

Ampoules Sodium Cacodylate-Endo, 0.13 Gm. (2 grains), 1 cc.: Benzyl alcohol 1 per cent is added for its local anesthetic effect.

Ampoules Sodium Cacodylate-Endo, 0.2 Gm. (3 grains), 1 cc.: Benzyl alcohol 1 per cent is added for its local anesthetic effect.

Ampoules Sodium Cacodylate-Endo, 0.3 Gm. (5 grains), 1 cc.: Benzyl alcohol 1 per cent is added for its local anesthetic effect.

Ampoules Sodium Cacodylate-Endo, 0.5 Gm. (7½ grains), 1 cc.: Benzyl alcohol 1 per cent is added for its local anesthetic effect.

THIAMIN CHLORIDE-ABBOTT (See New and Nonofficial Remedies, 1940, p. 529).

The following dosage forms have been accepted:

Tablets Thiamine Hydrochloride-Allett, 9 mg.: Each tablet contains 3,000 U. S. P. units of thiamine hydrochloride.

Tablets Thiamine Hydrochloride-Abbott, 12 mg.: Each tablet contains 4,000 U. S. P. units of thiamine hydrochloride.

SATURDAY, SEPTEMBER 21, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

THE CLOSED PLASTER METHOD OF TREATING COMPOUND FRACTURES AND INFECTED WOUNDS

The treatment of compound fractures and infected wounds during the war of 1914-1918 underwent numerous changes. The general trend was toward the local use of chemicals to kill the bacteria and check the sepsis. Carrel and Dakin, the last and most successful exponents of this trend, introduced on a large scale continued irrigation of the wound with sodium hypochlorite, the antiseptic property of which was combined with weak toxicity for tissues. The postwar contributions of Baer of Baltimore and of H. Winnett Orr of Lincoln, Neb., introduced a new principle in the treatment of these conditions, that of physiologic rest to the injured part. The principle is embodied in Orr's closed

plaster method, the essential feature of which is the complete immobilization of the soft tissues. No attempt is made to kill the organisms by external agents. The reliance is placed entirely on the ability of the body to resist bacterial infection.

The first large scale experiment in the appliance of these principles was made possible in the Spanish war. There chiefly owing to the enthusiasm of Trueta, chief surgeon of the General Hospital of Catalonia, the method was adopted in the medical service of the republican army. The total number of cases treated was 20,000. The incidence of gas gangrene and of other infections fell so definitely that foreign surgeons who came to Catalonia at the later stages of the war were led to believe that the soil of Spain contained no anaerobes.

The method, as described in Trueta's¹ recent monograph, is carried out in the following manner: Surgical treatment is undertaken as soon after occurrence of the fracture as possible; with the patient anesthetized, thoroughly wash the entire extremity and the wound with soap and water and a nail brush, shave all hair and paint the surrounding skin with a weak solution of iodine; excise the skin edges of the wound, remove all contused tissue and widen the wound; excise carefully and unhesitatingly all nonviable muscular and cellular tissues; open up the neighboring cellular surfaces affected by contusion, always keeping in mind the need for adequate drainage; remove all foreign material; reduce the fracture by traction on an orthopedic table; dress the wound with sterile gauze and immediately immobilize with plaster including the two adjoining joints if possible. The plaster is applied according to the method of Bohler directly to the skin, only the bony prominences being padded; administer 3,000 units of tetanus antitoxin. It is not permissible to cut a window in the cast, since this deprives the soft tissues of much needed immobilization. "It can be observed," says Trueta, "that the tissues swell into the gap in the plaster and their healing power is correspondingly weakened." This is in essence Orr's treatment with a single exception, namely that Trueta employs dry gauze as dressing for the wound instead of Orr's petrolatum pack. The plaster is left in position as long as the smell is not excessive and the plaster has not become soft and wet. It may be left in position for from four to six weeks and then replaced and left in position until such time as the fracture has healed.

Orr² obtained good results with this method in from 85 to 90 per cent of compound infected fractures in

1. Trueta, J. J.: *Treatment of War Wounds and Fractures with Special Reference to the Closed Method as Used in the War in Spain*, New York, Paul B. Hoeber, Inc., 1940.

2. Orr, H. W.: *Treatment of Compound Fractures with Special Reference to Military Surgical Procedures*, Arch. Surg. 40:825 (May) 1940.

civilian practice. The method, according to Trueta, is particularly adapted to conditions of modern warfare, in which in addition to the usual military casualties there are large numbers of civilians wounded by aerial bombardment. In Trueta's own material there were 1,073 cases of compound fractures of the limbs, most of them war wounds. There were six fatalities, 976 good or satisfactory results and ninety-one poor results. Trueta expresses the belief that no other treatment could have enabled them to alleviate for so many victims the horrors of war and air raids. Dr. Matas,³ who had an opportunity to observe the method in the Catalan war zone, writes: "I had an opportunity to see several plaster encasements removed from arms and thighs after they had been in situ for from fifteen to twenty-one days. The stench of the soiled encasement was nauseating. A magma or mush of decomposing pus and wound secretions covered the surface of the wound under the plaster bandage. But after washing this off with warm water and soap, and when the packs were removed, I was surprised to see the excellent, healthy, pink, well granulated appearance of the wound coupled with a very satisfactory condition of the patients—no fever, no pain, good appetite. This was indeed a revelation I did not anticipate." Matas quotes Dr. Jiménez of Banolas, under whose direction there were treated 6,000 fractures, of which 500 were fractures of the femur, with a mortality for the total group of 3.2 per cent. There was only one case of gas gangrene and this one had appeared before admission to the hospital.

The rationale of treatment is based on the following considerations: 1. Rest allows local veins and capillary thrombi to form. These prevent and delay the spread of infection and are not broken down by repeated handling. 2. Rest allows new capillaries to form which are not torn down by repeated dressing of the wound. 3. The plaster maintains a constant beneficial pressure on the wound; the calcium in it may be of local value much as the calcium gluconate exuded by the maggots according to Stewart. 4. The mixture of organisms on the wound may by their mutual antagonism prevent the victory of any one group. 5. To leave a deep wound uncovered produces dehydration and loss of heat leading to a condition of shock. The success of the method depends in a large measure on a thorough understanding of the underlying principles and rigid adherence to a meticulous technic. "It is fallacious to believe," warns Trueta, "that it suffices to enclose a wounded limb in a plaster of paris cast to achieve the benefits of closed treatment." He emphasizes that the method should be employed by those qualified by training to plan and undertake the first stages of the technic, which are purely surgical.

HISTAMINE AND ANAPHYLAXIS

Haag and Lutz,¹ of Düsseldorf, and Farmer,² of Lenox Hill Hospital, New York, have shown that anaphylactic shock may be decreased in severity by at least two types of antihistamine therapy. These demonstrations go far to settle one of the historic controversial questions in allergic physiology. Since the time of the late Victor C. Vaughan, speculative theories of anaphylaxis have centered around the question of secondary toxicity. Vaughan's original assumption that the dominant symptoms in anaphylaxis are due to "anaphylatoxins" formed by partial hydrolysis of parenterally injected foreign proteins was eventually discarded. It was replaced by the Dale-Laidlaw³ theory, which assumes that stored-up vasodilator substances are set free by the fixed tissue cells as a result of antigen-antibody reactions and that these freed histamine-like substances are the immediate cause of the typical allergic symptoms. This histamine theory has been subjected to extensive biochemical and physiologic research. A definite increase of histamine-like substances in the liver, spleen and bronchial musculature, for example, results from experimental protein sensitization. A liberation of these stored vasodilator substances follows local tissue injury. Bartosch and his co-workers,⁴ for example, applied perfusion methods to hypersensitive lungs and found that such substances are set free into the perfusion fluid as a result of allergic bronchoconstriction.

Physiologic assays have shown that relatively large amounts of histamine are normally present in the stomach wall. The walls of the small intestine in contrast are practically free from histamine. From this it has been deduced that there is presumably a histamine-destroying enzyme in intestinal tissues. This deduction has been confirmed by the recent extraction of a powerful histaminase from the normal intestinal mucosa. This enzyme has been tentatively standardized, the provisional unit being the amount of extract necessary to destroy or inactivate 1 mg. of histamine in vitro by the end of twenty-four hours' incubation at 37 C. Rose and Browne,⁵ however, found in the rat that histaminase occurs only in the lung and small intestine but that within fifteen minutes after intravenous injection of histamine the tissues contain more histamine than the blood. After fifteen minutes the rapidity of disappearance from the tissues occurs in the following order: blood, lung, lymph gland, liver and kidney. After thirty minutes the rate of disappearance is greater from the kidney than from the other tissues named. Adrenalectomy was shown to retard the rate of disappearance

of histamine from the tissues, especially the kidney. These results suggest that factors other than histaminase may defend the organism against the action of histamine.

If the Dale-Laidlaw theory of anaphylotoxin is correct, one might predict that this histamine-destroying enzyme injected parenterally would have prophylactic or therapeutic effects in anaphylactic shock. This prediction was tested by Haag and Lutz, who found that in guinea pigs a single intraperitoneal injection of one unit of this enzyme, given a few hours before the allergic test, greatly reduces the severity of the resulting anaphylactic shock. In no case, however, did such injection completely prevent the anaphylactic reaction, a result that was in accord with the Dale theory. Similar results have been obtained by Karady and Browne,⁶ who found that some animals not protected by the preadministration of histaminase survived large doses of histamine and egg white, the latter given to animals previously sensitized to this protein. The alleged prophylactic effect is presumably due to an enzymic reduction in the amount of available histamine in the fixed tissues.

A somewhat different method of therapeutic attack was made possible by Fuehner's⁷ observation that "refractoriness" to histamine can be induced in experimental animals by repeated parenteral injections of increasing doses of histamine. If the anaphylactic symptoms are due to fixed-tissue liberation of histamine, such histamine-refractory animals presumably would be relatively insusceptible to anaphylactic shock. In order to test this conclusion, Farmer gave a series of sensitized guinea pigs repeated intraperitoneal injections with histamine over a period of from twelve to eighteen days. He then tested the reactions of uterine strips from these animals by the routine Schultz-Dale technic, control tests being made with strips removed from sensitized guinea pigs that had not received histamine therapy. Titrations of allergic sensitivity showed that the uterine musculature of the treated guinea pigs was not only refractory to histamine but at the same time distinctly less sensitive to specific foreign protein. While 65 per cent of the control strips reacted to 1:250,000 dilutions of specific foreign protein, but 22 per cent of the treated strips reacted to this dilution. This suggests a threefold reduction in allergic sensitivity as determined by his arbitrary test dose.

Farmer afterward found that a similar though less effective histamine refractoriness with accompanying reduction in protein sensitivity can be conferred on guinea pigs by repeated oral administration of histamine. His effective antianaphylactic dose was 3 mg. of ergamine phosphate given by mouth at two to three day intervals over a period of two to three weeks.

Farmer's general conclusion from his data is that "histamine is the substance responsible for the anaphy-

lactic contraction of plain muscle." This is essentially a confirmation of the Dale-Laidlaw theory of anaphylaxis. The clinical value of induced histamine refractoriness in allergic disease, however, has not yet been determined.

Current Comment

THE SELECTION OF MILITARY PILOTS

Many factors enter into the proper choice of men who are qualified to fly combat planes, including age, inherent psychologic ability and, of course, such well recognized physical qualities as eyesight, coordination and sound cardiovascular functioning. Numerous problems are also involved in care of fliers after their training. Methods have been or are now being devised to detect potential "air neuroses," to counteract the effects of lack of oxygen due to high altitudes and to study countermeasures against the so-called black-out which apparently results from insufficient circulation to the brain during rapid descent. The subject is far too complicated for brief discussion but is receiving serious attention in such publications as the German Army's Medical Guide for Flying Personnel, in the book by Armstrong on the "Principles and Practice of Aviation Medicine" and even in such periodicals as the current issue of *Fortune*. The study of the entire subject requires the active cooperation of physiologists and physicists and has resulted in a new specialty in medical practice—the flight surgeon.

DEATHS FROM POISONING IN MASSACHUSETTS

About 10 per cent of the deaths certified by medical examiners over a ten year period in Massachusetts were recorded as due to ingestion of toxic substances, according to a recent study by Alexander and his co-workers.¹ There were in all 8,661 such cases. Of these 4,505 were directly related to the ingestion of ethyl alcohol, this substance being responsible for 52 per cent of all deaths due to poisoning in the medico-legal sense. Illuminating gas accounted for 21 per cent and "nontherapeutic chemicals" for 11 per cent. Carbon monoxide other than illuminating gas caused 8 per cent and surgical anesthetics 4 per cent of all fatalities due to toxic substances. Sedative drugs were responsible for 3 per cent and non-sedative drugs for 1 per cent of the deaths. Of the 271 deaths from sedative drugs 152 resulted from barbiturates, eighty-seven from alkaloids, including opium and its derivatives, eight from paraldehyde, six from chloral, six from bromides and twelve from undefined sedative drugs. Alcoholic individuals were represented in each of these groups. Of the total deaths from sedative drugs 56.1 per cent were accidental, 36.5 per cent suicidal, 16.2 per cent alcoholic and 17.4 per cent unknown. The most striking feature of the report is the high percentage of deaths from poisoning which are due to ethyl alcohol.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

MEDICAL REGIMENT TRAVELS THREE THOUSAND MILES

The First Medical Regiment, which for eighteen years had been stationed at the Field Service School at Carlisle Barracks, Pa., arrived in Camp Ord, California, June 28, after having marched 3,102 miles in fourteen days. The regiment averaged more than 250 miles each marching day and on some days made more than 300 miles. Almost the entire distance was made over U. S. Highway 40, although U. S. Highway 30 was followed through the mountains. The regiment consisted of seven officers of the medical corps and 180 enlisted men under the command of Lieut. Col. Robert P. Williams. The march was made without a single serious injury and only one slight accident to a motorcycle sergeant, who was struck by a civilian car.

INSTRUCTION IN AVIATION MEDICINE

A six weeks course of instruction to qualify physicians for military duty as medical aviation examiners was recently completed at the School of Aviation Medicine, Randolph Field, Texas, the commandant of which is Lieut. Col. F. L. Pratt, M. C. About thirty medical officers were enrolled for the course. The School of Aviation Medicine also conducted a resident course of instruction to qualify enlisted specialists which was attended by twenty-six enlisted men of the medical department, including one noncommissioned officer of the National Guard of Washington. The School of Aviation Medicine, in addition to resident courses, throughout the year, conducts extensive correspondence courses.

EXAMINATION FOR APPOINTMENT IN MEDICAL CORPS OF NAVY

Examinations for appointment as assistant surgeon and acting assistant surgeon (intern) in the Medical Corps of the U. S. Navy will be held Jan. 6-9, 1941, it is announced. The appointments as assistant surgeon in the regular Navy will be effective in about two months after the examination and those for acting assistant surgeon (intern) will be effective July 1, 1941. Requests for authorization to appear for these examinations should be submitted to the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., in time to permit the authorization to reach the applicant prior to December 30.

Applicants for appointment as assistant surgeon must be citizens of the United States between the ages of 21 and 31, must be graduates of recognized medical schools and must have completed one year of intern training in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association. Applicants for the appointment as acting assistant surgeon (intern) are not required to submit evidence of intern training and are appointed for eighteen months to serve as interns in naval hos-

pitals. After one year of service they are eligible for examination for appointment as assistant surgeons.

In the normal rotation of assignments, the naval officer's preference is given every practicable consideration for the type of duty he desires, according to the announcement. Officers are encouraged to develop a specialty after they have completed their first cruise at sea and provision is made for special training. Information about physical requirements, rates of pay and other details may be obtained by addressing the Bureau of Medicine and Surgery, Washington, D. C.

Appointments are also being made in the Medical Corps, U. S. Naval Reserve, of male citizens who are under 50 years old and who meet physical and professional requirements.

Applications for appointment to the Medical Corps of the Naval Reserve should be addressed to the commandant of the naval district in which the applicant resides. Addresses of the commandants may be obtained from the Bureau of Medicine and Surgery.

GRADUATES OF MEDICAL FIELD SERVICE SCHOOL

At the Medical Field Service School, Carlisle Barracks, Pa., in June graduation exercises were held for the second basic class, at which Brig. Gen. Roger Brooke of the U. S. Army Medical Corps, commandant of the field service school, delivered the address. All officers of the graduating class took part in the maneuvers of the third army at Fort Benning, Ga., and in the Sabine Area. Half of the graduating class were attached to medical regiments and battalions having these maneuvers and half were attached to regimental medical departments. These assignments were later alternated so that each student could get experience with the various medical units. The physician graduates of the Field Service School were as follows:

ORGANIZATION SECTION

OFFICIAL NOTES

COUNCIL ON INDUSTRIAL HEALTH

Report of July Meeting

The sixth meeting of the Council on Industrial Health took place on July 14, 1940, at the Palmer House in Chicago. Members in attendance were Stanley J. Seeger, chairman, Harvey Bartle, Leroy U. Gardner, Henry H. Kessler, Anthony J. Lanza, Robert T. Legge, C. W. Roberts, R. L. Sensenich (ex officio), Olin West (ex officio) and Carl M. Peterson, secretary. Also in attendance were Miss Joanna Johnson, chairman of the Industrial Nursing Section of the National Organization for Public Health Nursing, R. G. Leland, director of the Bureau of Medical Economics of the American Medical Association, and Paul A. Neal, acting chief, Division of Industrial Hygiene of the National Institute of Health.

Transactions of interest to the profession were as follows:

1. The Committee on Nomenclature reported further progress on material being collected for a compendium of terms used in the industrial health field.

2. The Committee on State Associations has continued to press for the appointment of cooperating committees in all state medical associations. There are now thirty-five such organized units. A uniform program has been submitted to these state committees and recommendations forwarded in respect to committee personnel. Active assistance will be sought from the organized state units in and through medical preparedness.

Attention will be called to the recent action of the House of Delegates relative to medical representation on boards administering workmen's compensation laws and regarding the preparation of fee schedules.

3. The Committee on Education and Publications submitted plans for the second Industrial Health Number of THE JOURNAL and for a series of special publications on medical service in industry and on occupational disease. A syllabus intended to assist in the development of adequate industrial medical education is now in preparation. The committee also reported recent improvements which have occurred in the field of undergraduate and postgraduate industrial medical education. During the past year exhibits have been prepared and demonstrated at medical society meetings and elsewhere.

4. The Council intends to continue to develop a clearing house of information on all industrial health matters. Methods of gathering and disseminating information were considered.

5. The census of physicians engaged in industrial practice recently made by the Council will shortly be augmented by data received through the Medical Preparedness Committee survey of medical personnel. To all such physicians a further questionnaire will be sent to determine qualifications for special industrial health assignments and special medical facilities now available.

6. The means for practical working relationships with the Committee on Industrial Dermatoses of the Section on Dermatology and Syphilology were discussed.

7. Lists of reliable textbooks and references are under preparation in the Council office as steps toward developing an industrial health bibliography.

8. The Council took note of the present status of legislation regarding industrial health under consideration in the present Congress.

9. The Council reviewed contacts recently established with other agencies interested in industrial health matters.

10. Plans were presented for the development of field work to make more effective the work of the Council and its cooperating committees in the state and county medical societies and to determine how the resources of physicians in the various states can be assembled and coordinated to constitute an effective health program in industry.

Attention was also directed to the contribution which a program of field activity could make to medical preparedness.

11. The Council received a report on syphilis in industry, preliminary to the development of a set of principles to be observed in the matter of case finding and management of syphilis among the employed population.

12. Attention was directed to the growing practice of industrial physical examination.

13. The subject of industrial nursing was considered, especially the means available to the Council for active assistance to the industrial nurse and industrial nursing organizations to improve the preparation and qualifications for an industrial nurse, to define proper functions, and to clarify all medico-nursing relationships in industry.

14. A memorandum is being drafted for submission to the International Association of Industrial Accident Boards and Commissions in the hope that that association will take favorable action on the development of uniform methods of statistical presentation of work done by the various state industrial commissions.

15. An extended discussion of medical preparedness occurred. The Council concluded that the best means for assisting the Committee on Medical Preparedness regarding industrial health which under existing circumstances gave the greatest promise of avoiding duplication of effort would be:

(a) To bring to the attention of the Surgeon General of the U. S. Public Health Service that

(1) The survey of physicians now being undertaken by the American Medical Association is paying direct attention to those available for service in industry.

(2) Additional information is to be sought from these same physicians about available medical facilities under their direction and about qualifications for special industrial activity.

(b) To request each member of the Council to submit suggestions promptly on methods of organization for effective work in the field of industrial health and that these suggestions be referred to the Committee on Medical Preparedness.

(c) To advocate the usefulness of field activity in relationship to medical preparedness.

16. Nominations were made and other plans laid for filling the existing vacancies in the membership of the Council.

17. A tentative program for the 1941 Congress on Industrial Health was submitted.

RADIO PROGRAM "DOCTORS AT WORK"

The winter and spring season of network radio broadcasting will be resumed by the American Medical Association in cooperation with the National Broadcasting Company over the Blue network of stations beginning Wednesday, November 13, at 10:30 to 11 p. m. eastern standard time (9:30-10 central, 8:30-9 mountain and 7:30-8 Pacific).

The program will be in dramatized form constituting the sixth successive season of dramatized broadcasting by the Association on a nationwide network. The title of the program will be Doctors at Work. The theme of the program will be the interpretation to the listener of services available in the treatment of disease and the preservation and promotion of health through the various branches of modern medicine. Thirty programs are planned dealing with different phases of medical practice, beginning with medical education, internship, residency and general practice and embracing all the major specialties in medicine and in medical phases of public health work.

The scripts will be written by William J. Murphy, director of continuity for the central division of the National Broadcasting Company, and will be under the supervision of the Bureau of Health Education with the cooperation of Miss Judith Waller, educational director, central division, National Broadcasting Company.

The evening hour assigned for these broadcasts is the most favorable hour that has ever been made available for sustaining health education broadcasts. Poster announcements of the pro-

grams have been prepared by the Bureau of Health Education. These will be sent in any reasonable quantity which can be effectively used on request from state or local medical societies and units of the Woman's Auxiliary or to health departments, schools or other educational institutions.

Titles of programs to come will be published three weeks in advance in *THE JOURNAL* and monthly in advance in *Hygeia*.

Comments on the program from physicians and other listeners are invited.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—The Conscription Bill, as agreed to by the Senate and the House, retains the provision providing for deferring the conscription of students, including medical students, the details of which provision were set forth in *THE JOURNAL* last week. The bill does not automatically defer the conscription of such students but provides that they be given a deferred status, on request. S. 3607 has passed the Senate, proposing a federal appropriation of \$75,000 for the fiscal year ending June 30, 1941, and for the five succeeding fiscal years federal appropriations increased at the rate of \$10,000 for each year, for use by the United States Public Health Service in conducting researches, investigations, experiments and studies relating to the cause, diagnosis and treatment of dental diseases, and to foster similar research activities by other agencies. S. 4245 has passed the Senate, authorizing the establishment of naval hospitals at the naval air stations at Jacksonville, Fla., and San Juan, Puerto Rico; the submarine base, Coco Solo, Canal Zone; the naval station, Guantanamo Bay, Cuba, and the marine barracks, Quantico, Va.

Bills Introduced.—S. 4314, introduced by Senator Hill, Washington, proposes to grant permanent total disability rating to veterans suffering from service connected tuberculosis disability if such disease remains active after two years' hospitalization. S. 4328, introduced by Senator Barbour, New Jersey, provides that no employer having contractual relations with the United States and engaged in the manufacture for or sale to the United States of supplies or equipment of any description shall dis-

criminate against any applicant for employment suffering from a physical disability, if such applicant shall have successfully completed a course of vocational training financed or directed in whole or in part by any agency of the United States government, and shall have been certified by such agency as qualified to perform the work for which he has applied. Such physically handicapped persons, the bill provides, shall not be entitled to preference in employment but shall be considered for any vacancy on an equality with applicants who are not physically handicapped. S. 4326, introduced by Senator Sheppard, Texas, provides for continuing in the Army, Navy, Marine Corps and Coast Guard of the United States, beyond the term of their enlistment, those suffering from service connected disease or injury and in need of medical care or hospitalization until recovery through such medical care and hospitalization.

DISTRICT OF COLUMBIA

Changes in Status.—H. R. 9284 has been reported to the Senate, directing the Commission on Licensure to Practice the Healing Art in the District of Columbia to issue a license to practice the healing art to Dr. A. L. Ridings, formerly of Sherman, Texas. H. R. 9525 has passed the Senate, providing for the reorganization of the government of the District of Columbia.

Bill Introduced.—H. R. 10418, introduced by Representative Boland, Pennsylvania, proposes to direct the Commission on Licensure to Practice the Healing Art in the District of Columbia to issue a license to practice the healing art to Dr. Peter Florey.

WOMAN'S AUXILIARY

Alabama

The auxiliary to the Calhoun County Medical Society has held regular meetings in Anniston during the year with an average attendance of twenty-five members. Subjects discussed and speakers thereon are as follows: "Proposed Project of Establishing Prenatal Clinic," Dr. J. M. Kimmey; "The Need of an Auxiliary in Each County," Mrs. W. M. Salter; "The Story of a Doctor's Wife," Mrs. N. T. Davie; "Longevity," Dr. J. M. Kimmey, and "Socialized Medicine," Mrs. James Britton.

At a meeting of the auxiliary to the Mobile County Medical Society in Mobile, Mrs. Percy Howard spoke on "Morals of Youth." The auxiliary has as its chief project the raising of funds for the institution for the prevention of tuberculosis in children.

The Talladega County Medical Society auxiliary has met regularly in Talladega. At the March meeting Mrs. A. F. Toole read a paper on "Doctors Through the Ages." The auxiliary provides linens and garments for the Citizens Hospital at Talladega.

Missouri

At the annual meeting of the auxiliary to the Missouri State Medical Association in Joplin recently addresses were given by Dr. Nathan B. Van Etten, President-Elect of the American Medical Association, Drs. James R. McVay and Cyrus E. Burford, president and president-elect, respectively, of the Mis-

souri State Medical Association, and Dr. Herbert L. Mantz, adviser to the auxiliary.

At recent meetings of the auxiliary to the Boone County Medical Society, speakers and their subjects were as follows: Dr. William Byrne Brown, director of the Stephens College Health Service, "Modern Trends in Medicine," and Dr. Fred McKinney, professor of psychology, University of Missouri, "Mental Health."

At a meeting of the auxiliary to the Cape Girardeau County Medical Society, Dr. A. C. Magill of State Teachers College spoke on "The Influence of Louis Pasteur on Medical Progress."

Dr. Milton D. Overholser spoke on "Laboratory Cancer Research" and Dr. Claude J. Hunt on "Effective Cancer Research" at the annual public relations meeting of the auxiliary to the Cass County Medical Society in Harrisonville.

Dr. J. C. Mulliniks spoke on "Our County Health Program" at the March meeting of the auxiliary to the Greene County Medical Society in Springfield.

Dr. R. C. Haynes spoke on "Problems Concerning the Medical Profession Today" at the March meeting of the auxiliary to the Saline County Medical Society in Marshall.

South Dakota

At a meeting of the auxiliary to the Fourth District Medical Society in Pierre recently it was voted to donate \$10 to the benevolent fund of the auxiliary and to place *Hygeia* in several of the schools of the Fourth District.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

First Councilor District Meeting.—The First Councilor District Medical Society will offer the following program at a meeting in Osceola, October 2:

- Dr. Charles H. Lutterloh, Hot Springs National Park, Gout.
- Dr. Francis Murphey, Memphis, Tenn., Ruptured Intervertebral Disk.
- Dr. Oliver C. Melson, Little Rock, Differential Diagnosis of Rheumatic Affections.
- Dr. Neuton S. Stern, Memphis, Acute Rheumatic Fever.
- Dr. Walter T. Swink, Memphis, Etiology of Chronic Arthritis.
- Dr. William C. Colbert, Memphis, Rheumatism as a Social and Economic Problem.
- Dr. Joseph F. Hamilton, Memphis, Use and Abuse of Physiotherapy in Chronic Arthritis.
- Dr. William C. Chaney, Memphis, Medical Treatment of Rheumatoid Arthritis.

CALIFORNIA

Extend Child Study.—The General Education Board has given \$61,700 to the Institute of Child Welfare of the University of California, Berkeley, permitting the continuation and extension of studies, already under way, on the mental and physical development of school children. Under the grant, a research center was to be opened September 1, supplementing the present offices of the institute. It will contain library facilities for the use of students in the field of child development and statistical and research offices for members of the staff, graduate students and other members of the university faculty. The grant will be administered under the direction of Harold Ellis Jones, Ph.D., director of the institute, and will cover a four year program. One of the specific studies deals with the analysis of physical changes as shown by growth in height and changes in body proportions, physiologic maturing as revealed by measurements of x-rays of the bones and assessments of physical ability and efficiency based on functional tests and laboratory records of physiologic changes during exercise.

DISTRICT OF COLUMBIA

New Reportable Diseases.—New regulations have been approved in the District to aid in the control of communicable diseases, newspapers reported August 13. Under the new disease code all persons in charge of hospitals, institutions or dispensaries are asked to report a communicable disease carrier to the department within twenty-four hours after discovery. All other persons knowing of a person afflicted with a communicable disease are likewise expected to report to the department. Forty-seven communicable diseases are specified in the code as reportable. Twenty-two of these are new, it was stated. The new regulations carry a penalty for violations. They were drawn in conjunction with the public health service and have the approval of the Medical Society of the District of Columbia.

GEORGIA

Personal.—Dr. Hugh J. Bickerstaff, Atlanta, associate director in the division of maternal and child health, state department of health, has resigned to become associate professor in public health administration at the Johns Hopkins University School of Hygiene and Public Health, Baltimore. Dr. Aldean Starr Ingram, Atlanta, was to succeed Dr. Bickerstaff in the department, beginning September 1.

Changes in Health Directors.—Dr. Chester A. Hicks, formerly of Ann Arbor, Mich., has been elected commissioner of health for the district composed of Bleckley and Dodge counties, with headquarters in Eastman. According to *Georgia's Health*, the formation of this district necessitates transferring Dodge County from the Southeastern to the East Central health region. Dr. Bert H. Malone, Waycross, has resigned as medical director of the Southeastern health region, effective August 1.

ILLINOIS

Society News.—Dr. Frank Deneen, Bloomington, discussed "Management of Some Types of Nonsurgical Goiter" before the Madison County Medical Society in Edwardsville, September 6.—The Pike-Calhoun County Medical Society was recently addressed at Barry by Drs. Andy Hall Jr. on "Urinary

Tract Infections"; Fred A. Kramer, "Vitamin Deficiencies and Their Relationship to the Gastrointestinal Tract," and J. William Thompson, "Surgical Management of Gastrointestinal Malignancy." All are of St. Louis.

Chicago

Dr. Oliver Appointed Professor of Dermatology.—Dr. Edward A. Oliver has been appointed professor and chairman of the department of dermatology and syphilology at Northwestern University Medical School. He succeeds Dr. Arthur W. Stillians, who was retired as of September 1 with the title professor emeritus. Dr. Oliver has been associate clinical professor of dermatology at Rush Medical College since 1927 and has been a member of the Rush faculty since 1912. He graduated at Rush in 1909. Dr. Stillians graduated at the University of Illinois College of Medicine in 1899 and has been professor of dermatology and syphilology at Northwestern since 1919.

Fellowship for Research in Rheumatic Fever.—The Chicago Heart Association, Inc., has received from the Clara A. Abbott Trust a gift of \$27,000 to be added to the Memorial Fund founded in memory of Morris Fishbein Jr. The money is to be used either by itself or with other funds of the society for the study and treatment of diseases of the heart and the circulation. A fellowship is to be established in a hospital or medical school in Chicago, which will be devoted primarily to the study of the cause and treatment of rheumatic fever. The Clara A. Abbott Trust has already donated millions of dollars to the University of Chicago, to Northwestern University and to the Evanston Hospital, since the purpose of the Clara A. Abbott Trust is to aid the care of the sick and the advancement of medical science. The Memorial Fund of the Chicago Heart Association, now almost \$40,000, was established in 1929 by Dr. and Mrs. Morris Fishbein at the time of the death of their son from rheumatic fever. The fund is administered by a self-perpetuating committee of five, including Drs. Robert B. Preble, Newell C. Gilbert, James B. Herrick, Walter W. Hamburger and Morris Fishbein. The officers of the society include Dr. Sidney Strauss, president; Dr. George K. Fenn, secretary, and Mr. Joseph L. Valentine, treasurer. The executive director is Mrs. Ruth McEldowney. Applications for the fellowship may be sent to the Chicago Heart Association, 203 North Wabash Avenue.

INDIANA

New Tuberculosis Hospital.—The new Southern Indiana Tuberculosis Hospital, near New Albany, was opened to patients August 19. The hospital cost \$650,000 and has a capacity of 150 beds. Dr. Jerome V. Pace, New Albany, is superintendent.

District Meeting.—The Eleventh Indiana Councilor District Medical Association will meet at Manchester College, North Manchester, October 2. The speakers will include Drs. Charles R. Bird, Indianapolis, on "Medical Preparedness and Service"; Elton R. Clarke, Kokomo, "Experiences in Conducting a Baby Clinic in Private Practice," and Harold M. Trusler, Indianapolis, "Burns and Their Treatment."

Courses in Obstetrics and Pediatrics.—The Indiana State Medical Association, the Indiana University School of Medicine and the bureau of maternal and child health of the state board of health are cooperating in a series of regional postgraduate courses in obstetrics and pediatrics. One group in obstetrics opened in Kokomo, September 6, under the auspices of the Howard County Medical Society, and one in Crawfordsville, September 12, under the direction of the Montgomery County Medical Society. A series in pediatrics began in Elkhart, September 5, sponsored by the Elkhart County Medical Society.

KENTUCKY

Changes in Health Officers.—Dr. Robert L. Loftin, Pikeville, recently health officer of Pike County, has been appointed health officer of a new unit in Harrison County, with headquarters at Cynthiana.—Dr. Edward W. Kissel, Paintsville, has been named health officer of Lawrence County, with headquarters at Louisa.

Society News.—Dr. Coleman C. Johnston, Lexington, addressed the Bourbon County Medical Society, Paris, August 22, on "Changing Trends in the Problem of Peptic Ulcer."—Trigg County physicians entertained the Christian County Medical Society in Cadiz, August 20, with Drs. Burton A. Washburn Jr. and Orion Leon Higdon, Paducah, as the speakers on "Diagnosis of the Acute Surgical Abdomen" and "Diagnosis and Treatment of Ectopic Pregnancy" respectively.

LOUISIANA

New Society of Pathologists.—The Louisiana Association of Pathologists was recently formed. Included among the officers are Drs. Edwin H. Lawson, president; Bela Halpert, vice president, and Andrew V. Friedrichs, secretary-treasurer. All are from New Orleans.

Changes in Health Officers.—Dr. Louis A. Breffleilh, Shreveport, has been assigned to the Lincoln Parish health unit as director to succeed Dr. Ralph H. Allen, Ruston, who has been transferred to Amite. Dr. Breffleilh has been doing similar work in Franklin, St. Mary's Parish.

MASSACHUSETTS

Personal.—Dr. John W. Chamberlain, Belmont, has been appointed assistant director of the department of hygiene at Massachusetts Institute of Technology, Cambridge. Dr. Chamberlain has been an assistant in the department since 1937.

Dr. Kimberly Named Director of Riggs Foundation.—Dr. Charles H. Kimberly, an associate of the Austen Riggs Foundation, Inc., Stockbridge, for the last six years, has been appointed its medical director, according to the *New York Times*. He succeeds Dr. Horace K. Richardson, who resigned. Dr. Kimberly graduated at Harvard Medical School, Boston, in 1924, has served on the staffs of several hospitals and has had postgraduate study in Europe. Established by the late Dr. Austen F. Riggs, the foundation provides free treatment for needy psychoneurotic patients.

MICHIGAN

Personal.—Dr. Edwin L. McQuade, in charge of the typhoid control program in the bureau of epidemiology, state department of health, has resigned, it is reported.—Dr. Willard L. Quennell, Detroit, for twenty years superintendent of the Highland Park General Hospital, resigned to accept the superintendency of the Norfolk General Hospital, Norfolk, Va., effective September 1. He was honored at a dinner, August 14, given by members of the Highland Park Physicians Club and the staff and board of managers of the hospital and was presented with a matched set of saddle leather luggage.

Industrial Surgeons' Meeting.—The Michigan Association of Industrial Physicians and Surgeons will hold its annual meeting in Detroit, September 24, with sessions at the Harper Hospital and the Book-Cadillac Hotel. Included among the speakers will be:

Dr. Carey Pratt McCord, Detroit, Responsibility of the Industrial Physician in Time of Military Mobilization.
Dr. Alfred H. Whittaker, Detroit, History of Industrial Medicine and Surgery.
Mr. Ben E. Kuechle, vice president and general claims manager of Employers Mutual Insurance Company, Wausau, Wis., Reporting Industrial Cases to the Insurance Carrier.
Mr. Frederick G. Palliaer, deputy commissioner, Michigan Department of Labor, Medical Testimony Before the Department of Labor.
Dr. Roy D. McClure, Detroit, Anoxia in Industrial Employees.
Dr. John Ewart Caldwell, Detroit, Evaluation of Disability.
Dr. John A. Caldwell, Cincinnati, Problems in Traumatic Surgery.
Dr. Grover C. Penberthy, Detroit, Surgery of Tendons.

At the dinner Dr. Frank T. McCormick, Detroit, president, will give an address. Other speakers will include Mr. Harvey Campbell, Detroit Board of Commerce, "Responsibility of the Industrial Physicians in National Defense," and Dr. George M. Curtis, Columbus, Ohio, "The Doctor Takes a Vacation."

Committee on Scope of School Health Services.—A new committee designed to outline the scope and policy of school health services has been appointed by Eugene B. Elliott, state superintendent of public instruction, Lansing. The committee will be asked to recommend what kind and what amount of responsibility the schools should assume for health services, and to point out the implications of these health service activities for health teaching; suggest specific health service responsibilities for teachers, administrators and school health specialists, and suggest the kind of factual information and experiences in the health service area that should be included in the teachers' college curriculum. Members of the committee are:

Dr. Eldred V. Thiehoff, state department of health, Lansing, chairman.
Dr. Clarence D. Barrett, Mason, director, Ingham County health department.
Vaughan Blanchard, Detroit, director, health and physical education.
Dr. Benjamin W. Carey, Detroit, Children's Fund of Michigan.
Otto W. Haisley, Ann Arbor, superintendent of schools.
Kenneth A. Easlick, D.D.S., Ann Arbor, University of Michigan Dental School.
Dr. Rockwell M. Kempton, Saginaw.
Dr. Matthew R. Kinde, Battle Creek, Kellogg Foundation.
Mildred Marshall, teacher, Walton Township school.
Ella E. McNeil, R.N., Ann Arbor, University of Michigan.
Dr. Joseph G. Molner, Detroit, department of health.
Harold H. Wilcox, Reed City, Osceola County commissioner of schools.

The Infantile Paralysis Situation.—Quarantines imposed to prevent the spread of infantile paralysis in Dickinson and Iron counties, where numerous cases have occurred in the outbreak in the upper peninsula, were to be lifted September 13, newspapers reported. No new cases had been reported for several days, it was said. Opening of schools at Newberry in Luce County has been postponed until September 30, and at Marquette on Lake Superior schools opened September 10 after a week's postponement. Delta County schools were to remain closed till September 16. At Hastings in Barry County in the southern part of the state schools were closed September 10 for the remainder of that week, although health officials advised that closing was not necessary. It was stated that twenty-one cases had occurred in the county since January 1, five since September 1. In Lansing one classroom was closed after one pupil was found to be ill with the disease. The number of cases in the state for the month of August was 301, compared with 385 in August 1939. The state health department made available an airplane for the use of physicians in reaching patients and for transportation of patients to hospitals. Drs. Sidney D. Kramer, head of the department's virus research laboratory, Lansing, and Jerome T. Jerome, Traverse City, of its orthopedic consulting staff, went to the area to be at the call of physicians and health officers.

MINNESOTA

Medical Continuation Courses.—*Minnesota Medicine* announces a series of medical continuation courses at the Center for Continuation Study, University of Minnesota, Minneapolis, beginning with one on anesthesiology, September 23-25. Others in the group are:

Health Problems of School Children, September 26-28.
Traumatic Surgery, September 30-October 5.
Medical Therapy in General Practice, October 7-12.
General Surgery, November 4-9.
Obstetrics, November 11-16.
Proctology, November 11-16.

As enrolment is limited, those wishing to participate in the courses should register as far in advance as possible, according to the announcement. Address Dr. William A. O'Brien, University of Minnesota Hospitals, Minneapolis.

MISSOURI

Personal.—The Cole County Medical Society met jointly with dentists and druggists of Jefferson City at a picnic barbecue recently to honor four men of the three professions who had completed fifty years of service. The guests of honor were Drs. John F. Jones, Linn; William D. Townley, Chamois; Albert E. Hammen, D.D.S., Jefferson City, and Mr. Henry DeWyl, Jefferson City. Dr. Townley, whose father and grandfather were physicians, has practiced medicine in Chamois since 1879. Dr. Jones is the son of a physician; he has practiced in Linn since 1889. Dr. Hammen has practiced dentistry in Jefferson City since 1888. Mr. DeWyl, a druggist for fifty-three years, now operates a drugstore which was founded by his father, a physician.

NEW YORK

Annual District Meetings.—The annual meeting of the Third District Branch of the Medical Society of the State of New York was held at the Colonial Country Club near Albany, September 17, with the following speakers:

Dr. Walter S. McClellan, Saratoga Springs, What Has Saratoga Spa to Offer in the Field of Therapy?
Dr. Albert F. R. Andresen, Brooklyn, Gastric Hemorrhage.
Dr. Temple S. Fay, Philadelphia, Observations on Human Refrigeration.
Dr. Charles H. Rammelkamp Jr., Boston, The Present Status of Sulfathiazole in the Treatment of Infections.
Dr. L. Whittington Gorham, Albany, Advances in the Specific Treatment of Pneumonia During the Past Year.

At the annual meeting of the Sixth District Branch at Ithaca, September 19, the speakers were:

Dr. John Maxwell Chamberlain, Oneonta, Recent Progress in Thoracic Surgery.
Dr. Benjamin P. Watson, New York, Clinical Use of Ovarian Hormones.
Dr. Cohn M. MacLeod, New York, Clinical Use of the Sulfonamide Drugs.
Dr. Thomas A. C. Rennie, Baltimore, The Psychoneuroses.
Dr. Thomas A. Gonzales, New York, Sudden and Unexpected Deaths from Natural Causes.

New York City

Fund Available for Research.—The New York Academy of Medicine announces that \$1,500 is available from the Louis Livingston Seaman Fund for research in bacteriology and sanitary science. The committee that administers the fund, established by the will of Dr. Seaman, will receive applica-

OREGON

State Medical Election.—Dr. William W. Baum, Salem, was named president-elect of the Oregon State Medical Society at the annual meeting in Eugene, September 4-7, and Dr. Karl H. Martzloff, Portland, was installed as president. Vice presidents are Drs. George E. Henton, Portland, reelected; Grover C. Belling, Salem, and John D. Rankin, Coquille. Dr. Morris L. Bridgeman, Portland, was reelected secretary.

PENNSYLVANIA

State Medical Meeting in Philadelphia.—The ninetyeth annual meeting of the Medical Society of the State of Pennsylvania will be held in Philadelphia, September 30 to October 3, under the presidency of Dr. Charles H. Henninger, Pittsburgh, and with headquarters at the Hotel Bellevue-Stratford. Guest speakers who will address general and section meetings will be:

Dr. Tom Douglas Spies, Cincinnati, Recent Advances in Vitamin Therapy.
Dr. Richard B. Cattell, Boston, The Management of Hyperthyroidism Complicated by Other Conditions.
Dr. Howard K. Gray, Rochester, Minn., Problems Associated with Surgery of the Biliary Tract.
Dr. Francis W. White, New York, Complications Incident to Paranasal Sinusitis.
Dr. Albert D. Ruedemann, Cleveland, Headache and Head Pain of Ocular Origin.
Dr. Borden S. Veeder, St. Louis, Pediatrics in Relation to the General Practitioner.
Dr. Lawson Wilkins, Baltimore, Studies of Hypothyroidism and Dwarfism in Childhood.
Dr. Eugene F. Traub, New York, Nev., Melanoma and Skin Cancer.
Dr. George Gilbert Smith, Boston, Total Prostatectomy for Carcinoma of the Prostate.
Dr. Frederick C. Irving, Boston, Results of Treatment of 1,000 Consecutive Cases of Preeclampsia.
Dr. Thomas B. Magath, Rochester, Minn., Hydatid Disease in North America.

Philadelphia

Society News.—At the first fall meeting of the Philadelphia County Medical Society, September 18, the guest speakers were Dr. Haven Emerson, New York, on "Public Health and the Private Practitioner" and the Rev. Alphonse M. Schwitala, Ph.D., St. Louis, on "The Hospital and the Private Practitioner." Dr. Rufus S. Reeves, retiring president, made an address and Dr. Edward L. Bortz was installed as president.

Appointments at Temple.—Dr. Waldo E. Nelson, assistant professor of pediatrics, University of Cincinnati College of Medicine, Cincinnati, has been appointed professor and head of the department of pediatrics at Temple University School of Medicine. In the latter capacity he succeeds Dr. Thomas F. McNair Scott. Dr. Nina A. Anderson, recently resident in pediatrics at the Children's and Cincinnati General hospitals in Cincinnati, has been appointed assistant professor. Dr. John B. Bartram, resident physician at the Children's Hospital, Cincinnati, will also join the faculty at Temple.

VIRGINIA

Personal.—Dr. Francis I. Bloise, Alexandria, has been appointed chief surgeon to the state prison system on a full time basis. The full time status was authorized by the 1940 General Assembly.—Dr. John Bolling Jones, Petersburg, has been appointed a member of the state board of health.—Dr. Herbert T. Wagner Jr., recently assistant director of the Roosevelt Hospital, New York, has been appointed superintendent of the Stuart Circle Hospital, Richmond.

Special Society Elections.—Dr. Waverly R. Payne, Newport News, was elected president of the Virginia Obstetrical and Gynecological Society at the annual meeting, which was held during the joint meeting of the state medical societies of Virginia and West Virginia at White Sulphur Springs, W. Va., in July. Drs. Andrew M. Groseclose, Roanoke, and Henry C. Spalding, Richmond, are vice president and secretary, respectively. Dr. John M. Bishop, Roanoke, was elected president of the Virginia Pediatric Society at the same time; Dr. Emily Gardner, Richmond, and Edwin A. Harper, Lynchburg, were elected vice president and secretary, respectively. Dr. Henry H. Wescott, Roanoke, was elected president of the Virginia Orthopedic Society and Dr. Bernard H. Kyle, Lynchburg, was reelected secretary. Officers of the Virginia Radiological Society elected were Drs. Wright Clarkson, Petersburg, president; Clayton W. Eley, Norfolk, vice president, and Charles H. Peterson, Roanoke, secretary. Officers elected by the Virginia Urological Society are Drs. Samuel B. Cary, Roanoke, president; Linwood D. Keyser, Roanoke, vice president, and Charles M. Nelson, Richmond, secretary.

tions from either institutions or individuals up to October 15. The fund will be expended only in grants in aid for investigation or scholarships for research in bacteriology or sanitary science. Expenditures may be for technical help, aid in publishing original work and the purchase of necessary books or apparatus. Communications should be addressed to Dr. Wilson G. Smillie, chairman of the committee, 2 East One Hundred and Third Street, New York.

New Administration Building at Bellevue.—A new administration building for Bellevue Hospital, built at a cost of about \$3,000,000, was dedicated September 11. Speakers at the ceremonies included Dr. Sigismund S. Goldwater, commissioner of hospitals; Dr. Charles D. Crandall, deputy medical superintendent, in the place of Dr. William F. Jacobs, medical superintendent, who was unable to attend; Mrs. Henry James, president of the board of managers of the school of nursing; Col. E. W. Clark, commissioner of public works for the Federal Works Agency, which contributed about \$1,500,000 toward the building; and Mr. Newbold Morris, president of the city council. Besides administration offices, the building provides, among other facilities, quarters for about 250 interns, administrative offices and classrooms of the school of nursing, Episcopal, Catholic and Jewish chapels. Bellevue now has a ground area of about twelve city blocks, on which are eighteen major hospital buildings. It has eighty-nine wards, with accommodations for about 2,500 patients. In these wards 68,485 patients were cared for in 1939. There are 660 physicians on the visiting staff. The nursing division consists of 980 graduate nurses, the school of women nurses with 421 students and a school for men nurses with 122 students in a summer course.

NORTH CAROLINA

Society News.—At a meeting of the Catawba Valley Medical Society in Hickory, September 12, the speakers were Drs. George Aubrey Hawes, Charlotte, on "Traumatic Urology"; George Carlyle Mackie, Wake Forest, "Shock"; Abner M. Cornwell, Lincolnton, "Surgery of Traumatic Injuries," and James W. Davis, Statesville, "Medical Preparedness."—Dr. Louis H. Clerf, Philadelphia, addressed the Guilford County Medical Society, Greensboro, August 1, on "Clinical Significance of Hoarseness in Relation to Cancer of the Larynx."

OHIO

Annual Regional Meeting.—The ninety-sixth annual meeting of the Northwestern Ohio Medical Association will be held at Ottawa, October 1. The speakers will be Drs. Jacob Victor Greenebaum, Cincinnati, on "Status of Immunization Procedures in Infancy and Childhood"; Julien E. Benjamin, Cincinnati, "The Experience and Treatment of Pneumonias During the Past Five Years," and Fred W. Rankin, Lexington, Ky., "Cancer of the Lower Gastrointestinal Tract."

Society News.—Dr. Marion W. Coleman, Dayton, addressed the Greene County Medical Society, Xenia, August 1, on "Cystitis in Women."—Drs. Frederic G. Maurer, Lima, and Charles L. Barrett, Bellefontaine, addressed the Auglaize County Medical Society, St. Marys, August 8, on "Rheumatic Heart Disease" and "The Medical Care Plan of the Farm Security Program" respectively.—Dr. Russell L. Cecil, New York, addressed the Academy of Medicine of Cleveland, September 20, on "Present Status of Serum Therapy and Chemotherapy in the Treatment of Pneumonia."—Dr. Harold N. Cole, Cleveland, addressed the Mahoning County Medical Society, Youngstown, September 17, on "Precancerous Dermatoses and Malignancy: Diagnosis and Treatment."

Postgraduate Lectures in Various Towns.—The Ohio State Medical Association announced its third annual series of postgraduate lectures to be held in the following towns: Napoleon, Tiffin, Mansfield, Warren, Cadiz, Athens, Columbus, Wapakoneta, Lebanon and Portsmouth. Twelve lectures will be given in each town in groups of four. About twenty lecturers will present the following subjects:

The Child and His Heart.
Meningitides in Children.
Clinical Approach to the Positive Mantoux Test.
Management of Heart Failure in the Home.
The Anemic Patient.
Deficiencies and Anemia.
Practical Uses of Sulfanilamide and Its Derivatives.
Modern Treatment of Pneumonia.
Complications of the Common Cold.
Childhood Ear Infections: Proper Treatment to Prevent Deafness.
Emergency Treatment of Roadside Injuries.
Fractures and Pseudofractures of the Spine.

The series opened September 18 in some towns and will continue to December 5.

WASHINGTON

State Medical Election.—Dr. George W. Cornett, Yakima, was named president-elect of the Washington State Medical Association at the annual meeting in Tacoma and Dr. Homer D. Dudley, Seattle, was installed as president. Dr. Lyle A. Greenwood, Bellingham, was elected vice president and Dr. Vernon W. Spickard, Seattle, was reelected secretary. The 1941 convention will be held in Seattle.

WEST VIRGINIA

Society News.—A symposium on syphilis was presented at a meeting of the Cabell County Medical Society, Huntington, August 8, by Drs. Ray M. Bobbitt, Boyd F. Brown and Edward F. Reaser. —Drs. Martin L. Bonar and Pat A. Tuckwiller, Charleston, addressed the Central West Virginia Medical Society, Webster Springs, August 21, on "Skin Manifestations of Internal Disorders" and "The Anxiety Tension State" respectively.

GENERAL

Fellowship for Research with Electron Microscope.—The National Research Council recently announced a new fellowship in electron microscope research established by the RCA Manufacturing Company for work to be carried on in the company's laboratories at Camden, N. J. It was announced that preference would be given "to versatile young men of United States citizenship, who have sound training in microbiology, a doctor's degree (Ph.D. or M.D.) and a record of original work." Applications are to be sent to the division of biology and agriculture, National Research Council, Washington, D. C.

American Public Health Association.—The sixty-ninth annual meeting of the American Public Health Association will be held in Detroit, October 6-11, under the presidency of Dr. Edward S. Godfrey Jr., Albany, N. Y., commissioner of health of New York State. Among addresses to be given in general and in section meetings will be the following:

- Dr. John R. Paul, New Haven, Conn., Rheumatic Fever—Factors in Its Occurrence.
- Dr. Clarence D. Selby, Detroit, The Renaissance of Industrial Hygiene.
- Dr. Cyrus C. Sturgis, Ann Arbor, Mich., Some Important Factors in the Etiology of the Anemias.
- Dr. John B. Youmans, Nashville, Tenn., An Assessment of the Nutrition of a Rural Population in Tennessee.
- Dr. Richard E. Shope, Princeton, N. J., The Silent Intermediate Host Reservoir as Exemplified in Bovine Pseudo-Rabies and Swine Influenza.
- Dr. Julius H. Hess, Chicago, Essentials in the Care of Premature Infants.
- Dr. Everett D. Plass, Iowa City, Organization, Supervision and Objectives of Prenatal Medical Supervision: Are They Being Met by the Average Prenatal Clinic?
- Dr. Henry E. Melency, Nashville, Tenn., The Recent Extension of Endemic Typhus Fever in the United States.
- Dr. Frank L. Horsfall Jr., New York, The Present Status of Knowledge Concerning Influenza.
- Dr. George Baehr, New York, Public Health Importance of the Intravenous Drip Method for Treatment of Syphilis.

At a special session Wednesday afternoon, October 9, on "The Control of Venereal Diseases in a National Defense Program" Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, Washington, D. C., will preside and speakers will include Major Gen. James C. Magee, Surgeon General, U. S. Army, and Rear Admiral Ross T. McIntire, Surgeon General, U. S. Navy, on the relationship of the health of civilians to the efficiency of their respective services. Dr. Waller S. Leathers, Nashville, Tenn., will be installed as president and will speak on "Public Health in National Defense." Henry F. Vaughan, Dr.P.H., Detroit, will give the second annual Delta Omega Lecture on "The Way of Health." The seventh Institute on Public Health Education will be held on Sunday October 6. Among speakers at general sessions will be Drs. William W. Bauer, director of the Bureau of Health Education, American Medical Association, Chicago, on "The Philosophy of Public Health Education," and Charles V. Akin, Washington, D. C., "The Status of Public Health Education."

Instruction in Nursing of Patients with Infantile Paralysis.—The National Foundation for Infantile Paralysis has published a pamphlet, "Nursing Care of Patients with Infantile Paralysis," by Jessie L. Stevenson, R.N., consultant in orthopedic nursing, National Organization for Public Health Nursing, New York. It is illustrated with line drawings showing various positions for the patient, apparatus and appliances for use in the acute stage and in convalescence. It was prepared by the public health nursing organization as a part of a project in orthopedic nursing sponsored by the foundation and is intended to assist the public health nurse and others responsible for home care of patients with infantile paralysis during

and following an epidemic. Copies are available free on request. Address the National Foundation for Infantile Paralysis, 120 Broadway, New York.

Meeting of Obstetricians, Gynecologists and Abdominal Surgeons.—The fifty-third annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons will be held at The Elms, Excelsior Springs, Mo., September 26-28, under the presidency of Dr. James R. McCord, Atlanta, Ga. Dr. Ernst James Heyman of Radiumhemmet and also docent in obstetrics and gynecology at the Caroline Institute in Stockholm, Sweden, will deliver the Joseph Price Oration. Dr. Erwin O. Strassmann, Houston, Texas, has received the association's Foundation Prize and will present his thesis on "The Theca Cone and Its Tropism Toward the Ovarian Surface, a Typical Feature of Growing Human and Mammalian Follicles." Among other speakers will be:

- Dr. Frederick H. Falls, Chicago, A Skin Reaction for the Diagnosis of Pregnancy.
- Dr. Charles O. McCormick, Indianapolis, The Effect of Obstetrical Anesthesia on the Newborn Infant.
- Dr. Clifford B. Lull, Philadelphia, Pubertas Praecox Due to Ovarian Tumors.
- Dr. David Hadden, Berkeley, Calif., Clinical Experience with Testicular Extract in Obstetrics and Gynecology.
- Dr. William A. Coventry, Duluth, Minn., Actinomycosis of the Ovary.
- Dr. Frank R. Smith, New York, Nativity and Carcinoma of the Cervix.

Conference on Tuberculosis.—The Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Sanatorium Association will meet at the Lowry Hotel, St. Paul, October 2-4. The program will include an x-ray conference, presided over by Dr. John H. Skavlem, Cincinnati, and the following papers:

- Dr. Jack Sanford Kruglick, Chicago, A Nationwide Survey of Food Handlers and Infections.
- Drs. William M. Kinney, Joplin, Mo., and Jesse E. Douglass, Webb City, Silicotuberculosis in Missouri.
- Dr. George McL. Waldie, Ispeming, Mich., Industrial Clinic Examinations.
- Dr. James D. Adamson, Winnipeg, Man., Canada, Examination of the Lungs in Recruits.
- Drs. Carl C. Birkelo and Bruce H. Douglas, Detroit, The 4 x 5 Film in Case Finding.
- Dr. David O. N. Lindberg, Decatur, Ill., Relative Usefulness of 35 Mm. Films in Case Finding.
- S. Reid Warren Jr., Moore School of Engineering, Philadelphia, Comparative Value of Chest Roentgenograms Made on Films and on Paper.
- William H. Feldman, D.V.M., and Dr. Archie H. Baggenstoss, Rochester, Minn., The Detection of Tubercle Bacilli in Latent Lesions and in Normal Tissues of the Human Lung.
- Dr. Herman E. Hilleboe, St. Paul, Tuberculosis in Public Institutions.

The Minnesota Public Health Association will hold its annual meeting in conjunction with the conference.

American Roentgen Ray Society.—The forty-first annual meeting of the American Roentgen Ray Society will be held at the Hotel Statler, Boston, October 1-4. At his installation as president of the society, Dr. Merrill C. Sosman, Boston, will speak on "Specialization in Roentgenology." According to the preliminary program there will be symposiums on diagnosis and treatment of carcinoma of the larynx; classification, treatment and prognosis of carcinoma of the thyroid; unusual forms of pulmonary disease; unusual gastrointestinal lesions and unusual sources of gastrointestinal hemorrhage. Miscellaneous topics will include:

- Dr. Robert Dranc, Savannah, Ga., An Unusual Intracranial Foreign Body.
- Drs. George M. Wyatt and Sidney Farber, Boston, Neuroblastoma.
- Dr. Karl Kornblum, Philadelphia, Polyostotic Fibrous Dysplasia.
- Dr. Barton R. Young, Philadelphia, Body Section Roentgenography (Planigraphy) in Diseases of the Respiratory Tract.
- Dr. Cornelius G. Dyke, New York, Cranial Laminography.

Dr. George W. Holmes, Boston, will receive the Caldwell Medal, Tuesday evening, following his delivery of the Caldwell Lecture on "The Development of the Science of Roentgen Technic." Gerry B. Schnelle, D.V.M., Boston, will deliver a clinical lecture on "Roentgen Rays in Veterinary Medicine" Wednesday afternoon.

LATIN AMERICA

Vital Statistics in Uruguay.—Forrest E. Linder, of the staff of the division of vital statistics of the Bureau of the Census, U. S. Department of Commerce, Washington, D. C., recently assisted the government of Uruguay to organize a statistical office in the ministry of public health. Transcript forms were prepared for civil mortality records, coding and tabulating procedures were developed and a manual of instructions for clerks was written, according to the Registrar, the bulletin of the census bureau. Mr. Linder made the trip as consulting statistician of the Pan American Sanitary Bureau. He visited also health agencies in Peru, Argentina, Brazil and Haiti.

Society News.—The First Brazilian Congress of Gynecology and Obstetrics was to be held in Rio de Janeiro, September 8-15. Subjects to be discussed were recent advances in gynecologic hormonology, diagnosis and treatment of cervical cancer, endocrinopathy in obstetrics and social aspects of obstetric assistance.—The second Latin American Congress of Criminology will be held in Santiago, Chile, Jan. 19-26, 1941, under the auspices of the University of Chile and the Institute of Penal Science. Among the subjects of medical interest to be discussed will be blood groups and their importance in criminology, classification of mental diseases with relation to their medicolegal importance, eugenics and criminology, psychoanalysis and criminology.

FOREIGN

Joseph Meister Dies.—Joseph Meister, the first person to receive the antirabies treatment from Pasteur in 1885, is reported to have committed suicide in Paris. Meister became Pasteur's assistant at the Pasteur Institute and after the scientist's death remained there as a guard.

CORRECTION

Superior Pulmonary Sulcus Tumor.—In the editorial "The Superior Pulmonary Sulcus Tumor of Pancoast" in THE JOURNAL, August 24, page 617, reference 5 in small type at the bottom of the second column should read: Steiner, P. E., and Francis, B. F.: Primary Apical Lung Carcinoma, *Am. J. Cancer* 22:776 (Dec.) 1934.

Government Services

Army Personals

Col. James E. Baylis, Medical Corps, U. S. Army, who for the last year has been executive officer in the Surgeon General's Office, was relieved of that assignment September 1 and ordered to Atlanta, Ga., where he will become corps area surgeon. The new executive officer in the Surgeon General's Office will be Col. Larry B. McAfee, who previously was executive officer at the Fitzsimons General Hospital, Denver. He will be succeeded by Col. Omar H. Quade.

Dr. Neal Made Chief of Division of Industrial Hygiene

Dr. Paul A. Neal, surgeon, U. S. Public Health Service, and a member of the staff of the National Institute of Health, Bethesda, Md., has been detailed as chief of the division of industrial hygiene of the institute, according to a recent release from the public health service. He succeeds Dr. Royd R. Sayers, who went to the bureau of mines several months ago. Dr. Neal, who is 39 years of age, graduated at Vanderbilt University School of Medicine, Nashville, in 1927.

Changes in Bureau of Animal Industry

The biochemical division of the Bureau of Animal Industry of the U. S. Department of Agriculture has been merged with the pathologic division and the animal nutrition division. The position of chief of the biochemical division has not been filled since the recent death of Robert M. Chapin. Activities of the division relating to animal diseases were transferred to the pathologic division and those relating to the nutritive value of animal products were assigned to the animal nutrition division at the Beltsville Research Center, Beltsville, Md.

Medicomilitary Training Course for Reserve Officers

The twelfth annual inactive status training course for medical department reserve officers of the U. S. Army and Navy will be held at the Mayo Foundation, Rochester, Minn., October 6-20. As in former years, special work in clinics and hospitals will be offered during the morning hours for those asking special assignments. Presentations of selected subjects in military medicine are scheduled. There will be appropriate sections or special courses for officers of the dental and veterinary corps. All medical department reserve officers on the

active list are eligible for enrolment. Approved applicants will be enrolled on the recommendation of the surgeon of the seventh corps area or the surgeon of the ninth naval district. Applications should be made at an early date and should be forwarded through the respective reserve headquarters of the officers concerned.

Navy Personals

Capt. Dallas G. Sutton, Medical Corps, U. S. Navy, has been ordered to duty in command of the Naval Medical School in Washington. Capt. Luther Sheldon Jr. has been ordered to duty as assistant chief of the bureau of medicine and surgery. Capt. William Chambers has been relieved from command of the Naval Medical School and ordered to command the hospital and school at San Diego, relieving Capt. Edward U. Reed, who goes to duty as medical officer of the twelfth naval district. Capt. George S. Hathaway was relieved from duty at the naval hospital in Newport and ordered to the Marine Corps base in San Diego.

Government Needs Medical Officers

The government needs medical officers. On August 5 the Civil Service Commission announced an examination for three grades of medical officer positions, ranging in salary from \$3,200 to \$4,600 a year, for a number of defense agencies as follows:

Public Health Service
Food and Drug Administration
Veterans Administration
Civil Aeronautics Authority
Indian Service

The examination includes fourteen different optional branches of medicine, giving opportunities to appointees to advance in their chosen specialty. Applicants will not be required to report for an assembled written test but will be rated on their sworn statements regarding their education, experience and fitness, subject to corroborative evidence. Applicants must have been graduated with an M.D. degree from a recognized medical school and must have had professional experience in one of the following optional branches:

- | | |
|---|--|
| 1. Aviation medicine | 10. Pathology, bacteriology and roentgenology (singly or combined) |
| 2. Cardiology | 11. Public health: |
| 3. Dermatology | (a) General |
| 4. Eye, ear, nose and throat (singly or combined) | (b) Venereal |
| 5. General practice | 12. Surgery: |
| 6. Industrial medicine: | (a) General |
| (a) Gas analysis or toxic dust | (b) Orthopedic |
| (b) General | (c) Chest |
| 7. Internal medicine and diagnosis | 13. Tuberculosis |
| 8. Medical pharmacology | 14. Urology |
| 9. Neuropsychiatry | |

For some positions in the Veterans Administration, applicants for positions of associate medical officer paying \$3,200 a year need not have had experience other than one year of internship.

The commission is finding it difficult to obtain enough qualified applicants for this examination. Applications will be received until further notice. The filling of these positions is of the utmost importance to the success of the national defense program, and physicians who are able to meet the announced requirements are urged to apply.

An examination has also been announced for two classes of junior medical officer positions paying \$2,000 a year (the one rotating internship, the other psychiatric resident positions) at St. Elizabeths Hospital, Washington, D. C. For the rotating internship positions applicants must be fourth year students in a class A medical school, but before entrance on duty they must furnish proof that they have successfully completed, prior to June 1941, a four year course in such a school. For the psychiatric resident positions applicants must have completed their fourth year of study in a class A medical school subsequent to Dec. 31, 1937, and must have a degree of B.M. or M.D. Before entrance on duty they must show that they have successfully completed an accredited rotating internship of at least one year. The closing date for receipt of applications is October 17 for states east of Colorado and October 21 for Colorado and states westward.

The requirements for all these positions are explained in detail in the examination announcements, which, with the application forms and further information, may be obtained from the secretary of the Board of U. S. Civil Service Examiners at any first or second class post office or from the U. S. Civil Service Commission, Washington, D. C., or from any of the commission's district offices.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug. 11, 1940.

Medical Service in Factories Made Compulsory

An order is to be made by the minister of labor which will require arrangements to be made in any named factory for part or whole time physicians, nurses and officers to supervise the welfare of the employees. The general council of the Trade Union Congress has welcomed the proposal as the beginning of a factory and welfare service. The council thinks that it might be extended so as to establish the principle of a state medical service.

Government to Pay Civilians for War Injuries

Air attacks have brought civilians into the same danger from air attack as soldiers and so the government has made similar arrangements both for the treatment of casualties and for payments for disablement from injury. The scheme for civilians applies to members of civil defense organizations injured while on duty and to all other civilians who depend on their earnings for a livelihood. It also applies to immediate dependents if the war injury is fatal. The grants in respect to injury are (1) a temporary injury allowance if the injury causes incapacity for work for not less than seven days; (2) a pension with family allowances if the injury results in serious or prolonged disablement. The temporary injury allowance for a married man is \$8 a week, for a single man \$5, for a woman \$4.50. Pensions for serious or prolonged disablement will be at the same rates as in the fighting services. For permanent disablement a man will receive \$8 a week, a woman \$6.

Our Health After Nearly a Year of War

In the *Sunday Times* Lord Horder takes stock of the health of the nation after nearly a year of war. While war is an evil thing, he thinks it has done good, like a hormone, in "activating the whole chemistry of the nation." It has had an accelerating effect on efforts we were making to improve the condition of the people. As far as physical health is concerned, Lord Horder finds that it has kept at an unusually high level. The comparative mildness of last winter's influenza epidemic was a blessing. Cerebrospinal fever, an epidemic hazard of wartime, though it showed itself in the early part of this year, died down quickly and chemotherapy reduced its fatality to an unprecedented level. None of the common infectious diseases attained serious dimensions. Tuberculosis has shown no material increase, and even "the camp follower of war," venereal disease, has not got out of hand. Deficiency diseases have not bothered us. For the control of all these plagues the intensified activity of the health services may take no small credit. The evacuation of children from the danger areas, concerning which so many fears were anticipated, was, from the health angle, a huge success. Compared with the previous year the incidence of diphtheria and scarlet fever fell to two thirds of that in 1938 and poliomyelitis to just over one third. The children benefited enormously in health.

This satisfactory condition of our national health Lord Horder ascribes much more to the increasingly favorable conditions of the people during the years preceding the war than to the care exercised during it. The contrast with Germany is marked. Dr. Gumpert, the author of "Heil Hunger," summarizes the results of six years of Nazi rule as "an increased death rate, a falling birth rate, growing criminality, an increase in drunkenness, venereal disease, tuberculosis, food poisoning and a doubling of mental disease." Gumpert considers Nazi rule "the most unwholesome political system ever born in the brain of man."

In physique we are far better prepared than was the enemy at the outset of war and we have kept well ahead of him. But now comes the testing time. Vigilance in health must include the worker as well as the fighter. That this is already apparent to the mind of the minister of health is shown by his memorandum on "Hours of Work and Maximum Output" and his exercise of emergency powers with regard to medical supervision of factories and the first aid and welfare services connected with them. The vital question of fatigue is being carefully watched.

WHERE BRITAIN LAGS

But, says Lord Horder, we must watch our national vices and repent of them in time. "We British are not scientifically minded; we pay lip service to research but are not really interested; method is not one of our national characteristics. Perhaps nature has spoilt us; anyway, in the absence of a strong incentive we are casual and lazy minded and we have left for a long time entirely unimplemented many of the discoveries that science hands out to us." As an example he gives neglect of immunization against diphtheria. It is some years since the principles of diet which underlie nutrition were established. Yet they are only beginning to be reflected either in the food of the people or in the kind of foodstuffs that the country produces. Now comes "total war" and so we must be efficient. We inquire how this is to be done and ask questions the answers to which have been shouted for years into deaf ears. We are turning to the experts and saying "Come, do your stuff; we need you." To their credit the experts do not resent our neglect and fail us. "Let a future generation say of this that it won the war because it realized the importance of guns and butter."

The Closing of the Burma Road and the Chinese Red Cross

The Chinese ambassador in London has received a telegram from Dr. Robert Lim, the distinguished pathologist and director of the Chinese Red Cross Medical Relief Commission, asking him to appeal to the British Red Cross, the British churches and the British government to exempt Chinese Red Cross equipment, supplies, vehicles and fuel in Burma from all restrictions in accordance with the spirit of the Geneva convention. If the passage of vehicles and fuel for medical relief is prohibited, the Chinese Red Cross will be deprived of all means of transporting medical material to the interior or running its ambulances. It may be remembered that the British government, under Japanese pressure at this critical time, consented to close the Burma road to the passage of munitions of war for three months, the suggestion being made that such closure would facilitate peace negotiations.

Dr. Hingston Fox, Balneologist

Dr. Hingston Fox, a leading balneologist, has died in his eighty-second year. Of Quaker stock he was the sixth in an unbroken line of physicians, the medical tradition of which is still preserved. His elder brother Richard Hingston Fox was, like him, a fellow of the Royal College of Physicians and was the medical historian of the Hunterian Society and author of "Dr. John Fothergill and his Friends." All his six brothers were physicians and also his son and daughter. Educated at the London Hospital, he specialized early in balneology, which he began to practice at Strathpeffer Spa in Scotland. On this he wrote a handbook and guide, "Strathpeffer Spa, its Climate and Waters." Eventually he settled in London, where he succeeded Sir Hermann Weber as the leading balneologist. He played a prominent part in the physical treatment of soldiers and sailors of the war of 1914-1918 who suffered from chronic arthritic complaints. He was honorary president of the *Ligue internationale contre le rhumatisme* and the founder and editor of the *Archives of the International Society of Medical Hydrology and Climatology*. He also wrote the "Principles and Practice

of Medical Hydrology," "Outlines of Medical Hydrology," "Physical Remedies for Disabled Soldiers" and "The Causation and Treatment of Chronic Rheumatism" (with Jan van Breemen of Amsterdam). A great pioneer of physical therapy, he experienced much of the disappointment of the reformer in a world, which will not share his enthusiasms.

BUENOS AIRES

(From Our Regular Correspondent)

Aug. 16, 1940.

Vitamin A Deficiency in Vascular Diseases

The question of vitamin A deficiency in vascular diseases was investigated in Buenos Aires by Prof. Dr. Mariano R. Castex in collaboration with his assistants Prof. Dr. Alfredo V. Di Cio and M. Schteingart, who made a report to the National Academy of Medicine. The vitamin A and the provitamin (carotene) contents were determined according to Linquist's technic in the blood serum of twenty-eight patients with vascular diseases and were compared with the normal values. In one half of the cases with intermittent claudication there existed a noticeable A hypovitaminosis of various degrees. Carotene underwent similar changes but in a smaller percentage. The results were even more noticeable in persons with gangrene of the lower extremities; in eight of these, only one had a normal value in the serum with the same proportionate reduction in carotene. The relationship of these changes to the vascular disease are not explained as yet.

Ulcerative Colitis and Spirochetes

The problem of colitis ulcerosa and spirochetes was investigated by Prof. Carlos Bonorino Udaondo, director of a large research laboratory in Buenos Aires, who reported the investigations in the *Archivos argentinos de enfermedades del aparato digestivo y de la nutrición*. Spirochetes are found in the stools of normal persons more frequently in tropical than in other regions of the globe. Whereas the diplostreptococcus of Bargen is found in numerous cases of chronic ulcerative colitis, the pathogenic character of spirochetes in the same disease is not as definitely established. It is assumed that the saprophytic spirilla of the saliva are swallowed and in the intestine, at sites which are already otherwise diseased, they become pathogenic; thus there are amebospirillar dysenteries and dysenterospirillar dysenteries. Among sixteen cases of ulcerative colitis there were seven in which the so-called diplostreptococcus and two in which *Spirochaeta eurygyrata* (Werner) was isolated. Oral and parenteral arsenic therapy, without other special treatment, produced cure within a few days. The spirilla, which previously were found practically in pure culture deep in the ulcerations, had disappeared. The value of this procedure is proved by a control case in which the arsenic therapy was unsuccessful, since few or no spirochetes were present.

Brief Items

In the early part of 1941 the second inter-American congress for endocrinology will be held in Montevideo (Uruguay), as had been decided at the first one in Rio de Janeiro. Dr. Juan C. Mussio Fournier, minister of public health, will be the chairman. All directors and deans of the faculties of medicine of American universities have been invited.

In Córdoba, provincial capital in northern Argentina, a cancer institute will be erected, for the construction of which 600,000 pesos (\$178,620) has been made available by the government.

Deaths

Prof. Carlos G. Malbrán died in Buenos Aires on August 1. He had made extensive bacteriologic and hygienic studies under Pettenkofer, Koch and Behring in Germany and under Roux in France. He was the first who held the chair for bacteriology

in Buenos Aires; he was president of the health department of Argentina and held other important offices. In 1899 he combated plague in Paraguay and introduced the organization for the control of leprosy in Argentina. He also did valuable work in the campaign against malaria.

Prof. Dr. Eduardo Rabello, a well known dermatologist, died in Rio de Janeiro, August 8. He was a member of the International Leprosy Committee, of the International League Against Venereal Diseases and founder and director of the Foundation Gaffrée Guinle. He also studied and published books on ancyllostomiasis, dermatomycosis, leishmaniasis and syphilis.

Marriages

ELLIS DUNCAN JR., Louisville, Ky., to Miss Marie Ernst Walmsley of Brooklyn at Falmouth, Mass., August 24.

FRED DAWSON REYNOLDS to Miss Violet Opal Barnett, both of Montgomery, Ala., at Memphis, Tenn., August 25.

JAMES BARCLAY DONALDSON, Jackson, Miss., to Miss Elizabeth Ann Gartner at Columbia, Tenn., August 21.

JAMES STERLING RUFFIN JR., Knoxville, Tenn., to Miss Kathryn Witherington of Covington, August 20.

FRANCIS CLABURN McLANE, Calhoun Falls, S. C., to Miss Mary Bowers Kinsey at Walterboro, August 10.

ANGELO WALTER BENJAMIN THEOBOLD CIANI, Iowa City, to Miss Ruth Bowman of Guttenberg, August 24.

VICTOR F. WOLDMAN, Cleveland, to Miss Carolin Mahler Heller of Cleveland Heights, Ohio, August 8.

JEAN KRUMRINE FIELD, Aliquippa, Pa., to Bernard Otis Black, D.D.S., of Toledo, Ohio, June 15.

ALBERT ERNEST RATH, Wooster, Ohio, to Miss Dorothy Paisley Snure of Lakewood, August 16.

TRAVIS SMITH, Winters, Texas, to Miss Mary Katherine Lewis of Houston at Temple, June 23.

JOHN AMOS CONLEY, Wilmette, Ill., to Miss Marie Natalie Cashatt at High Point, N. C., in June.

ALBERT ARCHER PARRISH to Miss Annie Marie McAdams, both of Durham, N. C., August 16.

JAMES W. TANKARD, Hilton Village, Va., to Miss Eileen Looney of Jenkins, Ky., in August.

MARCUS A. PIERSON JR., Galveston, Texas, to Miss Gladys Daly of Opelousas, La., in August.

W. VINCENT MEYER, Everett, Wash., to Miss Dorothy Gilmore of Butte, Mont., June 22.

LESLIE M. CHAFFEE, Coupeville, Wash., to Miss Edna Vander Stoep of Oak Harbor, June 24.

JOSEPH S. SKOBBA, to Miss Hope Toman, both of Indianapolis, in Fort Wayne, Ind., August 1.

WILLIAM H. HOLLINSHEAD, Minneapolis, to Miss Mary Waddell of St. Paul, July 16.

ERNEST C. ASBURY, New Baden, Ill., to Mrs. Josephine L. Asbury of O'Fallon recently.

WELDON P. CHANDLER, Asheville, N. C., to Miss Athylene Briggs of Mars Hill in June.

WALTER LEWINNEK, Mason City, Ill., to Miss Beryl Nelson of Antigo, Wis., August 12.

THOMAS N. MEADE, Goldendale, Wash., to Miss Roselia Turley of Yakima, June 22.

LAWRENCE H. MILLER, Bradford, Pa., to Miss Ann Thompson of Wilkesburg, June 15.

HERMAN HINDIN, Ritzville, Wash., to Miss Virginia Larse of Wenatchee, June 17.

HOMER B. GABLE, Monticello, Ind., to Mrs. Helen Bennett of Logansport, August 7.

JOHN JOSEPH FRANCIS to Miss Lidie Shaw, both of Nashville, Tenn., June 20.

CREIG S. HOYT JR., Grove City, Pa., to Miss Ruth E. Honk, June 18.

NED B. GRINER, Circleville, Ohio, to Miss Mary Agnes Thaw in June.

RODNEY B. HEARNE to Miss Dorothy Leede, both of Seattle, July 3.

Deaths

Robert G. Sayle, Milwaukee; Rush Medical College, Chicago, 1885; member of the State Medical Society of Wisconsin; fellow of the American College of Surgeons; past president of the Milwaukee County Medical Society; for many years on the staff of the Wisconsin College of Physicians and Surgeons and the Marquette University School of Medicine as instructor of anatomy, surgical anatomy and clinical surgery; surgeon to the Milwaukee, Milwaukee Children's, Johnston Emergency, and Deaconess hospitals; aged 80; died, August 1, of coronary occlusion.

Oscar Addison Mack McKimmie, Washington, D. C.; Columbian University Medical Department, Washington, 1891; member of the Medical Society of the District of Columbia; formerly clinical professor of laryngology and otology at the George Washington University School of Medicine; fellow of the American College of Surgeons; aged 72; attending surgeon to the Episcopal Eye, Ear and Throat Hospital, where he died, August 7, of uremia and cardiovascular renal disease.

Virgil Ernest Dudman Ⓢ Portland, Ore.; Northwestern University Medical School, Chicago, 1914; associate clinical professor of obstetrics and gynecology and formerly instructor at the University of Oregon Medical School; fellow of the American College of Surgeons; president of the Emanuel Hospital; on the gynecology staff of the Multnomah Hospital; on the visiting staff of St. Vincent's Hospital; aged 55; died, August 5, of subacute bacterial endocarditis.

Forbes Hawkes Ⓢ New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1891; member of the American Urological Association; fellow of the American College of Surgeons; consulting surgeon to the Presbyterian and Flower and Fifth Avenue hospitals, New York, Flushing (N. Y.) Hospital, Nassau Hospital, Mineola, St. Joseph's Hospital, Far Rockaway; aged 74; died, August 24, of coronary thrombosis.

Floyd Jerome Atwell Ⓢ Cooperstown, N. Y.; Albany (N. Y.) Medical College, 1907; member of the House of Delegates of the American Medical Association, 1937-1938; served during the World War; secretary of the Otsego County Medical Society; was town and village health officer; on the staff of the Mary Imogene Bassett Hospital; aged 55; died, August 24, of embolism following an operation for appendicitis.

Numa Pompilius Garfield Adams, Washington, D. C.; Rush Medical College, Chicago, 1924; dean since 1929 and professor of medicine since 1930 at the Howard University College of Medicine; at one time a member of the staff and director of the heart clinic at the Provident Hospital, Chicago; aged 55; died, August 29, in the Albert Merritt Billings Hospital, Chicago, of pneumonia following an operation.

Mary Elizabeth Halsall, Winthrop, Mass.; Tufts College Medical School, Boston, 1903; member of the Massachusetts Medical Society; aged 75; on the courtesy staff of the Winthrop Community Hospital, Chelsea (Mass.) Memorial Hospital, Whidden Memorial Hospital, Everett, and the New England Hospital for Women and Children, Boston, where she died, August 1, of bronchopneumonia.

Ralph Waldo Westhampton, N. Y.; University of the City of New York Medical Department, 1882; fellow of the American College of Surgeons; consulting gynecologist to the Lebanon and Jewish Maternity hospitals, New York, Nyack (N. Y.) Hospital, Rockaway Beach (N. Y.) Hospital and the Southampton (N. Y.) Hospital; aged 79; died, August 6, of arteriosclerotic heart disease.

Robert Warren Miller Ⓢ Los Angeles; College of Physicians and Surgeons, Keokuk, Iowa, 1876; Bellevue Hospital Medical College, New York, 1887; past president of the Los Angeles County Medical Society; for many years on the staffs of the California Hospital and the Methodist Hospital; aged 90; died, August 6, of cerebral hemorrhage.

Mary Jeannette Kearsley Ⓢ Chicago; Woman's Medical College, Chicago, 1888; past president of the Aux Plaines branch of the Chicago Medical Society; formerly on the staff of the Women's and Children's Hospital; for many years on the staff of the West Suburban Hospital, Oak Park, Ill.; aged 73; died, July 7, of coronary thrombosis.

Zebud MacKay Fliinn, Prescott, Ariz.; Dalhousie University Faculty of Medicine, Halifax, N. S., Canada, 1932;

served with the Canadian Army in the Royal Flying Corps during the World War; aged 41; died, August 3, in the Presbyterian Hospital, San Juan, Puerto Rico, of spontaneous subarachnoid hemorrhage.

Jacob Myer Berris, Detroit; Detroit College of Medicine and Surgery, 1917; member of the Michigan State Medical Society; assistant instructor in clinical medicine at the Wayne University College of Medicine; for many years on the staff of the Grace Hospital; aged 44; died, August 8, of coronary thrombosis.

Henry William Morsch Ⓢ Woodhaven, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1904; on the staffs of the Lutheran and Bushwick hospitals, Brooklyn; aged 57; died, July 30, in the New York Post-Graduate Hospital of coronary occlusion and prostatectomy.

Henry Levi Davis, Rockford, Ill.; St. Louis University School of Medicine, 1906; member of the Illinois State Medical Society; veteran of the Spanish-American War; aged 61; died, August 6, in St. Anthony Hospital of perforation of the esophagus and aorta due to a chicken bone which he swallowed.

James Meade Atkinson Ⓢ Eaton, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1893; on the staff of the Ball Memorial Hospital, Muncie, and the Blackford County Hospital, Hartford City; aged 77; died, August 12, of coronary occlusion.

Samuel Milton Wendt Ⓢ Chchalis, Wash.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1897; at one time health officer of Kittitas County; on the staff of St. Helen's Hospital; aged 68; died, August 1, of coronary disease.

Arno Edward Bohm, Akron, Ohio; University of Wooster Medical Department, Cleveland, 1907; member of the Ohio State Medical Association; served during the World War; aged 60; on the staff of the People's Hospital, where he died, August 12, of myocarditis.

Hubert Thomas Elders Ⓢ Lieutenant, M. C., U. S. Army, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1936; was commissioned a first lieutenant in the regular army in 1938; aged 33; was killed, August 18, in an airplane accident.

Wilson Randolph Ⓢ Detroit; Detroit College of Medicine, 1906; formerly associate professor of ophthalmology at his alma mater; fellow of the American College of Surgeons; on the staff of St. Mary's Hospital; aged 62; died, August 2, of coronary thrombosis.

Boney Wells Page Ⓢ Trenton, N. C.; Medical Department of Tulane University of Louisiana, New Orleans, 1909; first rural whole time health officer in North Carolina in Lumberton, Robeson County, from 1912 to 1917; aged 63; died, August 1, of heart disease.

Daniel Andrew Nolan Ⓢ Middletown, Conn.; Medico-Chirurgical College of Philadelphia, 1895; served during the World War; on the staff of the Middlesex Hospital; aged 68; died, August 2, of cerebral hemorrhage and diabetes mellitus.

Victor Bodine Ayers, Buena Vista, Colo.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; served during the World War; aged 69; died, August 5, in the Red Cross Hospital, Salida, of mesenteric thrombosis.

Walter C. Byrne, Elmira, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1892; member of the Medical Society of the State of New York; at one time county coroner; aged 70; died, August 15, of coronary occlusion.

Henry Clay Hornsby, Burning Springs, Ky.; Louisville Medical College, 1898; member of the Kentucky State Medical Association; aged 80; died, August 4, in St. Joseph Hospital, Lexington, of pyloric obstruction, probably carcinomatous.

Ivan King, Chicago; Chicago Medical School, 1928; Université de Genève Faculté de Médecine, Switzerland, 1932; member of the Illinois State Medical Society; aged 44; died, July 30, in the Michael Reese Hospital of pyelonephrosis.

Joseph Arda Hall, Cincinnati; Miami Medical College, Cincinnati, 1897; served during the World War; fellow of the American College of Surgeons; aged 67; died, August 8, at Sugar Hill, N. H., of a ruptured aneurysm of the aorta.

John Cornelius Shoudy Ⓢ Syracuse, N. Y.; Syracuse University College of Medicine, 1890; for many years a member of the staff of the Crouse-Ingers Hospital; aged 71; died, August 4, of coronary thrombosis and arteriosclerosis.

Lafayette Van Amburg, Jackson, Miss.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; aged 81; died, July 17, in the W. A. Foote Memorial Hospital of auricular fibrillation and arteriosclerosis.

Charles Edward Clingan, Sioux City, Iowa; Rush Medical College, Chicago, 1877; member of the Iowa State Medical Society; aged 89; died, August 8, on a ranch near Sundance, Wyo., of myocarditis and arteriosclerosis.

Samuel F. Haverstock, Detroit; Detroit College of Medicine, 1909; member of the Michigan State Medical Society; on the staff of the Lincoln Hospital; aged 59; died, August 9, as the result of an automobile accident.

Kenneth Parnell Foster * Gloversville, N. Y.; University of Buffalo School of Medicine, 1931; member of the Medical Society of the State of New York; aged 32; died, August 19, of a gunshot wound in the head.

George Henry Hooper * Belmont, Mass.; Tufts College Medical School, Boston, 1919; on the staff of the Cambridge (Mass.) Hospital; aged 49; died, July 24, of duodenal ulcer and mediastinal lymphoblastoma.

Frederick Albert Cook, East Aurora, N. Y.; University of the City of New York Medical Department, 1891; explorer; aged 75; died, August 5, in the New Rochelle (N. Y.) Hospital of cerebral hemorrhage.

William Hugh Carroll, Oak Terrace, Minn.; University of Minnesota Medical School, Minneapolis, 1933; aged 31; died, August 7, in the Eitel Hospital, Minneapolis, of subacute bacterial endocarditis.

Edward E. Carter, Arkadelphia, Ark.; Gate City Medical College, Dallas, Texas, 1905; member of the Arkansas Medical Society; aged 64; died, August 7, of cerebral hemorrhage and diabetes mellitus.

Rudolph Hanover, McKees Rocks, Pa.; Baltimore Medical College, 1906; member of the Medical Society of the State of Pennsylvania; aged 62; died, August 1, in the Montefiore Hospital, Pittsburgh.

Jesse Lane Wickle, Anniston, Ala.; University of Georgia Medical Department, Augusta, 1879; formerly mayor and state senator; aged 85; died, July 25, in a local hospital of chronic myocarditis.

Harlo Adoniram Fiske, Springfield, Mass.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1877; aged 89; died, August 8, of myocarditis.

Marietta C. Catalano-MacLean * Buffalo; University of Buffalo School of Medicine, 1923; aged 42; died, August 3, in the Millard Fillmore Hospital of peritonitis following a cesarean section.

William Roe Foard, Cumberland, Md.; Baltimore Medical College, 1903; aged 58; died, August 4, in the Allegany Hospital of injuries received when he was struck by an automobile.

John Campbell Tilt, St. Joseph, Mo.; St. Louis University School of Medicine, 1903; member of the Missouri State Medical Association; aged 70; died, July 30, of coronary occlusion.

Theodore Dwight Foljambe, Madison, Ohio; Cleveland Medical College, 1891; aged 70; died, July 29, in the Lake County Hospital, Painesville, of empyema of the gallbladder.

Thomas Dudley Merrick, Richmond, Va.; Jefferson Medical College of Philadelphia, 1888; member of the Medical Society of Virginia; aged 77; died, July 28, of paralysis agitans.

George Franklin Way * Lincoln, Maine; Bellevue Hospital Medical College, New York, 1897; formerly county medical examiner; aged 65; died, July 30, of angina pectoris.

J. S. Smith * Radford, Va.; College of Physicians and Surgeons, Baltimore, 1887; aged 78; died, July 23, in the New Altamont Hospital, Christiansburg, of myocarditis.

Reinhard Roerig, Parsons, Kan.; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, 1896; aged 73; died, July 11, in Independence of a fractured hip.

William Isaac Painter, Tazewell, Va.; Jefferson Medical College of Philadelphia, 1894; member of the Medical Society of Virginia; aged 70; died, July 20, of heart disease.

Merton Elbridge Rideout * Waupaca, Wis.; Northwestern University Medical School, Chicago, 1904; aged 63; died, July 22, of coronary sclerosis and arteriosclerosis.

William L. Wise, Chopin, La.; Memphis (Tenn.) Hospital Medical College, 1903; member of the Louisiana State Medical Society; aged 64; died, July 24, of heart disease.

Thomas Dennis Kelly, Miami, Fla.; Columbia University College of Physicians and Surgeons, New York, 1919; aged 46; was found dead, July 29, of coronary occlusion.

Cornelius M. Dailey, Carnegie, Pa.; Baltimore Medical College, 1905; aged 63; died, August 19, in the Harrisburg (Pa.) Hospital of glomerular chronic nephritis.

Edgar A. Peck, Valparaiso, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1880; aged 82; died, August 10, of bronchopneumonia.

Frances Wallach Monell, Great Neck, N. Y.; New York Medical College and Hospital for Women, New York, 1889; aged 89; died, July 13, of arteriosclerosis.

Andrew Lyman Paey, Norfolk, Va.; Meharry Medical College of Walden University, Nashville, Tenn., 1905; aged 65; died, July 27, of arthritis deformans.

Walter H. Allen, Alta, Ill.; Barnes Medical College, St. Louis, 1897; aged 79; died, August 16, in St. John's Hospital, St. Louis, of carcinoma of the kidney.

Richard H. Speight Jr., Rocky Mount, N. C.; University of Maryland School of Medicine, Baltimore, 1901; aged 61; died, July 31, of coronary thrombosis.

Park Laurimore Berkshire, Lewisport, Ky.; Barnes Medical College, St. Louis, 1901; aged 65; died, July 28, of cardiorenal disease and hypertension.

Bernard Thomas Colglazier, Kansas City, Mo.; Kansas City College of Medicine and Surgery, Kansas City, 1921; aged 46; died, July 5, of heart disease.

Alvah Henry Jensen * Hutchinson, Minn.; University of Minnesota Medical School, Minneapolis, 1925; aged 44; died, July 8, of coronary thrombosis.

Jacob Edgar Mendelsohn, Akron, Ohio; Maryland Medical College, Baltimore, 1912; aged 55; died, July 23, of coronary disease and diabetes mellitus.

Edward Chase Cook * York Village, Maine; Medical School of Maine, Portland, 1894; aged 70; died, July 9, of cardiovascular renal disease.

Charles Judson Sawyer * Windsor, N. C.; College of Physicians and Surgeons, Baltimore, 1895; aged 72; died, July 28, of coronary thrombosis.

Emily Wright, Springboro, Ohio; Woman's Medical College of Pennsylvania, Philadelphia, 1889; aged 80; died, July 13, of carcinoma of the rectum.

Harry Edward Barco, Blackstone, Va.; Howard University College of Medicine, Washington, D. C., 1911; aged 58; died, July 27, of carcinomatosis.

Albert P. Rocquet, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1889; aged 74; died, July 18, of nephritis.

William Abner Wyatt, Rosie, Ark.; Barnes Medical College, St. Louis, 1899; aged 74; died, July 12, of hypertension and arteriosclerosis.

Jefferson F. Landen, Chinquapin, N. C.; University College of Medicine, Richmond, Va., 1905; aged 78; died, July 16, of coronary occlusion.

Everett A. MacDonald * Beverly Hills, Calif.; Medical College of Ohio, Cincinnati, 1895; aged 69; died, August 3, of coronary occlusion.

John Franklin Kirksey, Mayfield, Ky.; University of Louisville Medical Department, 1897; aged 65; died, July 28, of cerebral hemorrhage.

Jacob Aldrich Wood, Syracuse, N. Y.; Albany (N. Y.) Medical College, 1873; aged 92; died, July 21, in Constantia of lobar pneumonia.

Eugene A. Brown, Brewster, N. Y.; Hahnemann Medical College and Hospital, Chicago, 1878; aged 92; died, July 12, of arteriosclerosis.

William Ross Johnston * Charlottesville, Ind.; Medical College of Ohio, Cincinnati, 1891; aged 73; died, August 8, of heart disease.

Charles Weakley Parker, St. Louis; University Medical College of Kansas City, Mo., 1891; aged 74; died, August 8, of heart disease.

Charles Fremont Hatcher, Ames, Iowa; Drake University Medical Department, Des Moines, 1888; aged 82; died, July 26, of uremia.

John Elliott Payne, Afton, Iowa; College of Physicians and Surgeons, Keokuk, 1896; aged 67; died, July 25, of heart disease.

Bureau of Investigation

SOME FRAUDULENT "CANCER CURES"

Science and scientific medicine continue to advance rapidly, in spite of which fraudulent "cancer cures" seem to go on forever—until some are overtaken by the United States Post Office Department or other federal agencies. In recent months the Post Office has caught up with some of these swindles and debarred them from the mails.

SAURINOL OIL AND SALVE

The Saurinol Distributors Corporation and John H. Olmes, Secretary, at Colorado Springs, Colo., and John H. Olmes at Pueblo, Colo., sold products through the mails under the false representations that when used as directed they would overcome and cure exposed cancer and many other conditions.

The Post Office memorandum brought out that some of the Saurinol advertising bore the claim that "This booklet is not issued to deceive or mislead the public, but as a guide for the user to administer 'Saurinol.'" Apparently unimpressed by this declaration of virtue, the Post Office proceeded with its investigation. From one Adam Griesener, President, and John H. Olmes, Secretary-Treasurer of the concern, the information was obtained that Saurinol Oil was the unrefined product of three wells located in Fremont County, Colo., and that the salve was prepared for the promoters by a chemist in Colorado Springs. A government chemist brought out that his analysis of the liquid Saurinol showed it to be a burning mineral oil containing 0.09 per cent of cinchona alkaloid, with a small amount of asphalt and a trace of ichthyol and the Saurinol Salve to contain 1.6 per cent of camphor and turpentine in a base of petrolatum and beeswax, with traces of paraffin and ichthyol.

Expert medical testimony introduced at the hearing showed that, aside from forming a protective covering for skin lesions both the Saurinol products would act merely as astringents and counterirritants and would be without therapeutic effect in the treatment of any cases of cancer or the other disorders for which they were promoted. The expert testimony also brought out that adequate treatment of any of these conditions must be based on proper diagnosis and remedies suited to the individual patient. Further, it was shown that in cancer the affected tissues must be subjected to microscopic examination prior to treatment by surgery, radium or roentgen ray, in accordance with the needs of the case.

According to the Post Office memorandum, inquiries addressed to the Saurinol concern after the Post Office investigation had begun also resulted in the receipt of replies soliciting remittances in the name of B. H. Rouse, M.D., at Florence, Colo. (Benjamin H. Rouse of Florence, Colo., appears in the American Medical Association's records as a graduate of Loyola University School of Medicine, Chicago, in 1919. He was licensed to practice in Illinois in 1920 and obtained reciprocal licenses in Idaho, Kansas, Nevada and Colorado.) In spite of the fact that Rouse had replied to inquiries sent to the firm, he denied any connection with the sale of the Saurinol nostrums. His letters to the Post Office Department indicated that in addition to Saurinol Oil and Salve he might furnish other treatment. Since the exact character of such treatment had not been ascertained, inclusion of his name in the fraud order was not deemed advisable by the Post Office.

The order was issued Feb. 29, 1940.

It is also worth noting that another government agency had earlier taken action against the concern. In July 1939 the Food and Drug Administration seized in interstate commerce a consignment of Saurinol that had been shipped by the Saurinol Distributors Corporation and charged that false and misleading statements on the label representing it as a relief from exposed cancer, varicose veins, pyorrhea, ulcers, skin diseases and some other disorders were a violation of the Food, Drug and Cosmetic

Act. Government chemists reported that the stuff was essentially medium boiling petroleum oil. As the Saurinol concern put up no defense the shipment was confiscated.

THE GRAFANOL FRAUD

From Durant, Okla., an outfit operating under the titles Grafanol Company and Grafanol Corporation, and run by one W. F. Grafa, sold "Grafanol Ointment" through the mails under the false and fraudulent representations that it was a highly effective remedy and cure for any case of skin cancer and many other disorders, chiefly those of the skin. The concern also sold by mail something called "Maytubby Springs Sour Water," which it fraudulently represented as a highly effective remedy and cure for any case of stomach trouble, kidney trouble, rheumatism or eczema. Names secured in various ways were solicited with circular matter which abounded in testimonials purporting to come from persons who had been "cured" by Grafanol.

A government chemist reported that Grafanol was a black viscous mixture of petrolatum products, water, sand and calcium oxide. The government's medical expert testified that the stuff would not and could not cure any case of cancer or blood poisoning.

The government chemist also analyzed Maytubby Springs Sour Water and testified that it contained 0.156 Gm. per hundred cubic centimeters of sodium sulfate, with traces of chloride, iron and other minerals, not named. The medical expert mentioned also testified regarding this water, stating that it would have no therapeutic action whatever, that its use was merely equivalent to the taking of an equal quantity of ordinary tap water and that it would not or could not overcome or cure stomach trouble, kidney trouble or eczema.

The fraud order was issued May 23, 1940.

An outfit known as R. F. Grafa & Sons, Durant, Okla., which may have been an earlier name for the same concern, was declared by federal authorities in 1932 to have violated the Pure Food and Drugs Act in fraudulently representing on the labels of its Grafanol Ointment that this was a remedy for skin cancer and many other disorders. The case was described in Notice of Judgment 19029, issued in July 1932.

SUSSMAN'S DIETARY "CANCER CURE"

"Buy my book and cure your cancer" might well have been the advertising slogan of one Ben Sussman of New York, who, operating as the Lufen Publishing Co., put out a volume "My Fight Against Cancer." The claims it contained were so obviously fakish that the Post Office Department declared its sale to be a scheme for obtaining money by means of false and fraudulent pretenses, representations and promises and debarred it from the mails.

According to the Post Office memorandum on this case, Sussman had been successively a life insurance agent, a real estate salesman and, from 1907 to 1922, the operator of a woman's apparel store. In the latter year, it appears, he retired from active business because of an illness which was described in some detail in his book. The first mention it made of cancer was as follows:

In 1927 and 1928, I was treated by an eminent skin specialist for a cancerous growth on the back of my neck and cysts back of my ears. This treatment consisted of X-Ray and Radium and I was considered cured. A few years later, some of the old trouble came out on my back and under my arm pit.

In the meantime, a sister-in-law of mine passed away of cancer, and my wife had been sick for a number of years with tumor and cancer. We went to Saratoga every year for treatment. We had used the best doctors, but to no avail. . . .

Sussman reluctantly divulged the name of the specialist mentioned. When this physician was asked by the government for the facts, he replied that he had treated the man between October 1926 and March 1930 for a pedunculated keloidal growth on his neck and various other conditions, but nothing of a malignant nature, nor was there any cancerous or other serious condition involved.

A few years after the foregoing treatment, according to Sussman, "some of the old trouble came out on my back and my arm pit." He later referred to this "old trouble" as being warts, wens, pimples or cysts, any of which, he asserted, was in his view the same as cancer or cancerous growth! His book relates his quest for a cure:

... I went again to Saratoga, took the baths and treatments, and again come in contact with some of the greatest men from all parts of the world and also with some of the best doctors. They . . . advised me that if I could acquire the knowledge of nutrition and food chemistry of the different elements and ingredients that certain foods contain in their natural state, I would be able to correct many of the ill results which abuse of my body had caused to develop, (over a long period of years). Since that time I have been searching far and wide and reading all kinds of books on cancer. I also attended numerous lectures and health classes conducted by doctors. I discovered that the real cure depended upon myself, providing I had the will power and backbone to do away with the old habits of living, and had the knowledge of how to live today, forget the past, and think only of the present.

After every so-called treatment, for the last 20 years, had failed me, I gave myself completely over to science and Mother Nature. With this aim in mind, I made many different experiments upon myself in the past six years, and watched the reactions to the ways of living which I had adopted for myself. Today, thank God for the wisdom and understanding of body chemistry, as I near my sixtieth birthday on December 23rd next, I feel better and look better than I did 20 years ago.

Thus, says Sussman's book, he cured himself by his vegetable and fruit diet of

all sorts of toxins, tumors and cancerous growths that had developed in me. Actually they were blocking the intestinal tract for the past 20 or 25 years. . . . I was able to dissolve all the impurities contained in my body for a number of years, from the combination of natural chemical elements of vegetables, such as carrots, pure grape fruit juice, garlic, celery, limes or lemons, watercress, parsley, cabbage, onions, spinach, beets, escarole, orange juice, seedless grapes, and black mission figs, soaked over night.

I used carrot juice with certified milk and a little evaporated milk, according to taste, about a quart a day, and I found this to be the most alkaline food for one suffering from tumors or cancer. Within a few weeks I realized that the pains in my stomach and in my entire body were gradually disappearing.

Because some statements made by Sussman at the government hearing contradicted some of his others as to the periods when he suffered from the declared disorders, his testimony was found to be so irrational as to deserve little if any credence. For that reason the acting solicitor for the Post Office Department who handled this case was convinced that Sussman had never had cancer. When Sussman was questioned about the various items in the diet that he claimed had "cured" him, he was unable to give intelligent answers. Further, although he claimed he had read "all kinds of books on cancer," he could not definitely identify even one such book, nor could he explain how "clogging" of the intestines could supposedly cause cancer. Also he was unable to explain why he drew a distinction between what he called cancer and cancerous growth, or the difference between a benign and a malignant tumor, or between a tumor and a cancer. Finally he admitted that all these terms meant the same to him. Typical of his erratic testimony was his assertion that although he regarded cancer as first in the order of maladies causing fatalities in this country he did not consider it a "serious disease." Although he claimed to base his "cure" on combinations of vegetables and fruits, he was unable to name even the primary constituents of foods: carbohydrates, fats, proteins, vitamins and minerals.

Expert medical testimony introduced at the hearing showed, according to the Post Office Department, that if persons having cancer undertook the treatment Sussman recommended, the result would be early and in many cases unnecessary death of such persons. The expert testimony also brought out that the only method by which a suspected cancer can be positively diagnosed as such is by means of a microscopic examination of the tissue surgically excised from the growth—a fact utterly unknown to Sussman—and that only scientific treatment can eradicate the cancer.

As Sussman conducted his swindle under the title of the Lujen Publishing Co., the fraud order issued March 7, 1940, unfortunately covered only this name and not that of Sussman as an individual.

Correspondence

ERROR IN WORK ON INFANTILE PARALYSIS

To the Editor:—My attention has recently been called to the fact that in volume A 40 of the International Bulletin dealing with Infantile Paralysis, published and distributed in the United States by the National Foundation for Infantile Paralysis, Inc., there is a statement on page 75 in French and on page 79 in English that is exceedingly ambiguous. This reads "Thus, he was led to the conclusion that 0.10G. of potassium chlorate, per kilo of body weight, given in syrup of raspberry, every two hours, during the daytime and at night, proved to be the optimal dosage."

This is not to be interpreted to mean that 0.10 Gm. of potassium chlorate is to be administered every two hours. This would be far in excess of the maximum tolerated dosage. This statement should be interpreted as being a total of 0.10 Gm. of potassium chlorate given, if at all, in twelve divided doses over a period of twenty-four hours.

TREATMENT OF DIABETES

To the Editor:—It was with dismay that we read in THE JOURNAL, August 10, statements of Dr. Edward Tolstoi at a conference of "the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments" regarding the treatment of diabetes. He said:

We found that our experimental subjects were free from the symptoms of diabetes in spite of glycosuria when they were receiving a diet of 75 Gm. of protein, 60 Gm. of fat and 200 Gm. of carbohydrate, and protamine zinc insulin in daily doses of 50 units. Two rather unusual patients whom we observed in the metabolism ward for periods of fifty to sixty days maintained their weight. I want to emphasize this point. They also had no thirst or polyuria; they had no ketonuria, and they were in nitrogenous equilibrium in spite of the fact that they excreted as much as 150 Gm. of sugar some days, and in spite of the fact that there was an ever present postprandial hyperglycemia. From such experiments we postulated that for patients treated with protamine zinc insulin the guiding features of satisfactory treatment should be (1) the maintenance of weight, (2) freedom from symptoms and (3) absence of ketonuria. Furthermore, we were not concerned about the hyperglycemia or the amount of dextrose excreted.

Does it make common sense to say that an adult of average body build and activity receiving 1,640 calories, daily in the form of carbohydrate 200, protein 75 and fat 60 Gm. who is excreting 150 or even 100 Gm. of sugar in twenty-four hours, thus leaving a net balance of 1,040 or 1,240 calories respectively, could maintain body weight and be in nitrogenous equilibrium for a prolonged period? Furthermore, is it sensible or economical to allow the wastage of so large a part of the food eaten?

According to Dr. Tolstoi, the patients were free from thirst and polyuria in spite of marked glycosuria. Let it be assumed, then, that the quantity of urine was normal and therefore approximately 1,500 cc. daily. If the patient voids 150 Gm. of sugar the proportion of sugar in that day's urine would be 10 per cent. Does it seem at all likely that the average diabetic patient will be symptomless while continuously excreting 10 per cent, or even 5 per cent, of sugar?

Progress in diabetes during the last fifty years has been by painstaking research. Certain bizarre methods of treatment have been introduced, but no successful method has totally disregarded facts. Each new method promulgated by responsible

physicians has been supported by data which, even though they might not convert others to the new idea, at least commanded respect. No matter whether the diet is high or low in carbohydrate, protein or fat or in total calories, the outstanding clinicians in this and other countries have sought to control the disease and in so doing have borne in mind the Naunyn dictum that the patient with severe diabetes, if carefully treated, is apt to do surprisingly well but the patient with mild diabetes, if neglected, does poorly.

Like many others, we believe in controlling the hyperglycemia of diabetes (1) because it is fundamentally an abnormal state, (2) because a high blood sugar is a constant stimulus for insulin secretion and allows no opportunity for rest and recuperation such as the pancreas of a healthy person enjoys between meals and at night and (3) because control of hyperglycemia and glycosuria proves utilization of the diet whereas their disregard leads, in our experience, to accessory annoyances such as polydipsia and polyuria, the attendant necessity for extra food to make up for the loss of calories in the urine and the obvious wear and tear on the system for ingestion, assimilation and excretion of this unutilized extra food, quite apart from needless cost and waste. A high percentage of sugar in the blood implies the same in the tissues; we think it likely that, directly or indirectly, this conduces to lack of normal tissue repair and resistance to infection, predisposes to degenerative phenomena in arteries and nerves and leads to weakness, weariness and impotence, although we freely admit that positive proof is lacking that all these harmful effects are due to hyperglycemia per se. Unhesitatingly we maintain that the blood sugar should approach normal because it is an index of the control of the diabetic condition; if normal, it is one assurance that the whole disease is being treated well. Hyperglycemia is the red light which the physician should no more disregard, although he cannot always explain its significance, than he should fail to heed the red signal at the railroad crossing because he cannot see the train around the corner.

Dr. Tolstoi's advice for certain cases of diabetic acidosis follows:

First, let us consider the one whose condition is not far advanced, the patient as we see him in the clinic. He may report a sore throat. Examination of the urine reveals a 4 plus acetone reaction and diacetic acid. The skin and the tongue are dry, acro is dehydration and there are listlessness and the desire to be left alone. We tell the patient "Go home, take a tablet or two of table salt (1 Gm. of salt) every hour, and follow that with a glass of water; in addition, take all the hot salt broth you can." We teach him to examine his urine for acetone and tell him to do so every two hours, and as long as acetone is present to give himself insulin (regular soluble) after each urine examination until the acetone bodies disappear. The dosage of insulin is determined by the urine analyses for sugar. He is told to take 25 units if the result of the test is yellow or red, 15 units if the specimen is green, and the juice of an orange if the Benedict solution is unchanged after boiling. This simple rule also protects the patients against insulin overdosage.

We condemn such advice. In our opinion it is dangerous to send home patients whose urine gives a 4 plus reaction for acetone and diacetic acid. Dr. Tolstoi does not even suggest that they keep under the supervision of their family physicians. If there is one thing we attempt to do as a result of our experience with patients in coma and near coma, with diabetic children and with diabetic patients in general, it is this—to train them, if any unusual symptoms occur, to call the doctor. A patient who exhibits "listlessness and the desire to be alone" is not likely to carry out intelligent, energetic self treatment.

We believe in the orthodox treatment of diabetes. We are convinced that our patients and the patients of other physicians do the best who follow the rules. Differences in diets of from 50 to 75 Gm. of carbohydrate a day are immaterial. By no means can we keep all our patients sugar free, but we do strive to maintain them under as good control as possible,

thereby, as we believe, protecting them from complications and progression of the disease. Furthermore, as will appear in the forthcoming (October) (seventh) edition of the "Treatment of Diabetes Mellitus," we have endeavored to support our convictions by recording the complications, the causes of death and the duration of life in 5,669 of our fatal cases between 1898 and 1940. Tables show the decrease of deaths due to coma from 64 per cent to 4 per cent, the steady increase in duration of life after onset from 4.9 to 12.5 years and the advance in the average age at death from 44.5 to 64.8 years.

"METABOLISM OF IRON"

To the Editor:—In an editorial in THE JOURNAL, July 27, various claims were made for a method of following iron metabolism, making use of radioactive iron. The editorial writer appears to have overlooked a communication published in the November 1939 issue of *Physical Review* (Barnett, Abraham: The Use of Radioactive Forms of the Common Elements in Physiology, *Physical Rev.* 56:963, 1939) casting serious doubts on the validity of conclusions drawn as to the behavior of nonradioactive metals from experiments carried out in which radioactive forms of the same elements are used. Briefly, taking the red cell as an example, it was pointed out that, since it is known that its limiting membrane is composed of an electrically charged polar lipoidal substance having a thickness estimated to be of the order of one molecule, the bombardment of the cell wall at close range by electrically charged particles emanating from the radioactive ion might alter the polar properties of the wall and so modify its permeability. Moreover, the proteins in contact with the cell wall are known to be denatured by beta rays such as are given off by radioactive iron, and denaturation of intracellular proteins might grossly alter the behavior of the thin surface membrane.

It would appear that there is an urgent need for determining whether or not radioactive ions are capable of altering the permeability of cell membranes; otherwise the large amount of work now being published on the use of radioactive "tracers" may prove grossly misleading. Unfortunately, access to radioactive forms of the common elements is limited and the costly equipment necessary for studying them not always available. It is suggested that an answer to the various questions raised here might be found by the following simple experiments:

1. The electrophoretic migration speeds of red cells suspended in isotonic nonradioactive and radioactive sodium chloride or Ringer's solution containing these ions could be compared. A difference in speed would argue in favor of a modification of the charge on the red cell by the radioactive sodium.

2. The impedance of the two solutions in the low alternating current frequency range (10,000 down to about 10 cycles per second) could be compared. A difference in either the reactive or resistive components would argue in favor of modification of the membrane (Fricke, H., and Curtis, H. J.: The Electric Impedance of Hemolyzed Suspensions of Mammalian Erythrocytes, *J. Gen. Physiol.* 18:821 [July] 1935. Cole, K. S., and Curtis, H. J.: Electrical Impedance of Nitella During Activity, *ibid.* 22:37 [Sept. 20] 1938). Since changes in permeability of the red cell membranes are reflected best by measurements at low frequencies (Fricke and Curtis), a simple comparison of impedances at 60 cycles might suffice.

ABRAHAM BARNETT, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HIGH PROTEIN DIET—OBESITY

To the Editor:—With regard to the question of meat in the diet, has any one cited absolute proof that "eating meat twice a day is harmful, increases blood pressure in a normal person, or decreases length of life by some way or other, usually believed to be by hurting the kidneys"? May I have an opinion on this? An argument arose because of a 23 year old man, some 20 pounds overweight, who is attempting to diet and eats meat twice a day. It is stated that he can't do much reducing because 50 per cent of his protein intake is converted to dextrose. Incidentally, the suggestion that he take magnesium sulfate twice a week to aid him brought the objection that it might derange his now perfectly normal morning habitual stool. Can you answer this? The suggestion that I watch his pulse, blood pressure and heart and give 2 grains of thyroid a day was voted down by his wife. I feel that my knowledge of his condition does not necessitate taking a basal metabolic rate and that thyroid in the amount suggested and continuance under my care could not be harmful. (The patient's parents both have low basal metabolic rates and are taking thyroid substance.) A check-up twice a week would forestall any impending harmful effects. (Of course 2 grains of thyroid a day is just to increase his metabolic rate and is not his tolerance dose.)

M.D., Ohio.

ANSWER.—There is no real evidence that the amount of protein which could be consumed by the average person using ordinary foodstuffs (even if he ate meat twice a day) would "increase the blood pressure, harm the kidneys or decrease longevity in any other way." Such evidence as does suggest a possible harmful effect is based on the use of artificial diets containing dried animal proteins, in rats. These observations are based on extreme experimental conditions and highly refined criteria for judging the results. Their application to man and their clinical significance, even if applicable, are doubtful. On the other hand, there are experimental observations on men who lived on an exclusively meat diet for a year without any detectable ill effects. In this connection it must be remembered that meats contain large amounts of fat, and that even an exclusive meat diet need not contain as large a proportion of animal proteins as can be incorporated in an artificial diet by the use of dried proteins. A review and bibliography of this subject was published by Bischoff in the *Journal of Nutrition* 5:431 [July] 1932.

The fact that a certain proportion of ingested protein is converted to dextrose has no bearing on the matter of weight reduction. Unless the sugar so formed is lost to the body (as may occur by excretion in the urine of a patient with uncontrolled diabetes) the ultimate caloric value of the ingested protein is independent of the intermediary metabolic processes which it may undergo. Whether an individual gains or loses weight, therefore, depends strictly on the balance between the total calories ingested in the form of any and all foodstuffs and the total calories expended during the same period, chiefly in the form of muscular work and heat.

The crucial importance of the balance between calories taken in and calories expended also determines the answers to the questions regarding the use of magnesium sulfate and thyroid. Each of these substances might cause some temporary loss of weight, provided the patient did not increase his food intake correspondingly. But the use of magnesium sulfate is not justifiable because (1) it produces its chief effect by dehydration, and the apparent weight loss can be restored by drinking a few glasses of water; (2) if used to excess it can interfere with food absorption, it may cause an enteritis, and will probably interfere with the regular stool habit; (3) it cannot be continued indefinitely as a treatment. The use of thyroid, except in instances of definite clinical hypothyroidism which apparently the case in question is not, is not to be commended because (1) it does involve possible harmful effects and (2) it cannot be continued indefinitely. It is the last reason in each case which is the most important objection to the use of these substances in the treatment of obesity. If weight reduction is accomplished by any temporary expedient without affecting the amount of food which the patient habitually consumes, it is obvious that he will gain back all the weight he has lost as soon as the treatment is suspended. The only real and permanent treatment for obesity when a patient is otherwise normal is the substitution of a new and better food habit for the old habit of overeating.

FLOOR FURNACE IN OPERATING ROOM

To the Editor:—A small addition to my hospital includes in the operating room (10½ by 12½ feet) a floor furnace built by the Coleman Lamp and Stove Company having an input of 20,000 British thermal units and an output of 14,000. We have a thermostat to control it and keep it at any desired temperature. Is it necessary to turn the furnace off while operating? Would it be safe if the pilot light alone was kept burning? My object in asking these questions is that my anesthesiologist requested that the furnace be turned off and the pilot light be extinguished before starting the anesthetic (ether). I understood before installing the furnace that it was safe for the purpose. Please advise me.

J. Guild Wood, M.D., Weatherford, Okla.

ANSWER.—It is well known that ether vapor is a little over two and one-half times as heavy as air. This means that ether vapor during anesthesia will flow from the point of administration to the floor and will then follow the drift of floor currents. It is understood that cold air from the floor is sucked to the outer jacket of the Coleman heater, where it comes in contact with the stove, and when warmed will form a shaft of hot air in the center of the steel register. Thus, the direction of circulation is from the floor with its high concentration of ether vapor to the hot stove. Exactly what mixture of ether and air will prevail will vary from minute to minute depending on the amount of administration and the technic used (opened or closed). Limits of flammability of ether-air mixtures range from 1.85 to 36.5 per cent by volume. Thus, with such a wide range, ether-air mixtures must be considered flammable.

The next point of interest is the minimum ignition temperature of ether-air mixtures. The United States Bureau of Mines states that this temperature is 304 C. Thus if the inner core of the heating system approaches or exceeds this temperature, it would cause ignition of the ether-air mixture which would necessarily come in contact with it.

An additional interesting fact is that the volume of air rendered explosive by 1 pound of ether at 60 F. and under one atmosphere of pressure is 277 cubic feet.

So far, only normal satisfactory working conditions for the Coleman stove have been considered. But the possibility of leaks in the stove and circulating mechanism or of possible back-fire must not be overlooked. Under such conditions, an open spark might easily explode an ether-air mixture.

It is therefore believed on purely theoretical grounds that the suggested use of the Coleman heater in an operating room where ether is the anesthetic agent is not without danger.

All figures cited are from the Explosion Division, Pittsburgh Station, U. S. Bureau of Mines (Jones, G. W., chemist: The Explosion and Fire Hazard of Combustible Anesthetics).

INTRAVENOUS ALCOHOL FOR ALCOHOLIC ADDICTS

To the Editor:—I would appreciate any information available about the injection of alcohol for the treatment of alcohol addicts. An article came out in the *Magazine Digest* of December 1939 condensed from an article in *Je sais tout*, Paris, by Joseph Andrieu, in which it is said "It is common to inject 40 cc. of alcohol (20 cc. in the morning and 20 cc. at night) which is ordinarily bought at the pharmacists." After two days' treatment the patient is supposed to be considerably improved and after five days he is cured.

R. W. Mann, M.D., Toronto, Ont.

ANSWER.—In the September 1939 issue of *Je sais tout*, a popular French magazine, is an article by Joseph Andrieu, D.Sc., concerning the treatment of chronic alcoholism. Andrieu gives Dr. Bruel credit for the theory that the morbid symptoms in chronic alcoholic addicts are due to withdrawal of alcohol and that a steady supply of alcohol tends to keep these persons apparently normal (Bruel, L.: Campaign Against Chronic Alcoholism: Intravenous Injections of 30 Proof Alcohol, *Echo méd. du nord* 10:497 [Aug. 31] 1939. Santa Cruz Salazar, Edilberto: Intravenous Alcohol, *Crón. méd.* 55:17 [Jan.] 1938). Bruel's treatment consists in the intravenous injection of 15 per cent alcohol by weight (30 degrés—probably about 30 proof), 50 cc. the first day and decreasing to 20 cc. on the fifth. "No pain or after effects are noted." Four out of five are said to be cured.

It is true that alcohol may eventually cause changes in the nervous system which are manifested by extreme unrest; more alcohol is then taken because the narcotic action of alcohol counteracts the nervousness, and so a vicious cycle is established. There is no doubt that a person who is at the verge of delirium tremens is temporarily benefited by alcohol, regardless of the method of administration. As the value of giving alcohol to alcoholic addicts is to prevent sudden withdrawal with subsequent onset of delirium tremens (a state in which much damage is often done to the patient) if the patient cannot consume alcohol by mouth, it would seem rational to give it intravenously, gradually decreasing the dose each time, similar to the way in which withdrawal of alcohol by mouth is accomplished. Until more concrete evidence is available, it is advisable not to become too enthusiastic over Bruel's treatment.

BELL'S PALSY AND SYPHILIS

To the Editor:—A man aged 38 has a left sided Bell's palsy of three weeks' duration which was found to be of syphilitic origin; both the Kohn and the Wassermann reaction have been positive on two different occasions. He has also had severe pressure points just posterior to the left ear. I have been giving him antisyphilitic treatment consisting of bismuth subcitrate and potassium iodide. Is this the proper routine to follow? What type of syphilis could this be without any history of a primary or secondary lesion? A spinal fluid examination has been flatly refused by the patient. When, if ever, is electrical stimulation necessary? Is massage of definite value in such cases? What is the usual rate of improvement in these cases and what is the prognosis?

M.D., Illinois.

ANSWER.—This man evidently is syphilitic but in the absence of a spinal fluid examination it cannot be taken for granted that the facial paralysis is due to syphilis. Facial paralysis of the ordinary peripheral type, so-called Bell's palsy, is common both in healthy people and in people who have some other disease. If any other cranial nerve is affected or if there are any cerebral symptoms, one would assume that syphilis is the cause. To make a prognosis and decide on the mode of treatment it is well to test the facial nerve and the muscles supplied by it with the faradic current. If there is normal response the prognosis is good for recovery within a few weeks, with or without treatment of any kind. If the response is lost it is well to give the muscles treatment every day or two with the galvanic current by means of an interruptor handle. Faradic treatment is, of course, useless. Massage of the face muscles is of some use in lessening the amount of atrophy by improving the circulation in the muscles. The treatment used for the syphilis may suffice if there is no involvement of the nervous system but the patient ought to be told about the serious risk he runs by not submitting to spinal puncture at this time when any eventual involvement of the nervous system might still be checked. If he persists in refusing spinal puncture it would be advisable to treat for syphilis in addition to the other remedies. If spinal puncture is made and the fluid gives a positive reaction, tryparsamide would probably be the drug of choice.

EOSINOPHILIA WITH GASTROINTESTINAL SYMPTOMS

To the Editor:—A married woman 36 years old has an irrelevant family history. Her own past history is essentially noncontributory except for her first pregnancy, the child being stillborn at 7 months. She subsequently had two normal labors. Her chief complaint, ten weeks ago, was pain across the upper abdomen, arising in the epigastrium and radiating to the right and left hypochondrium. The character was described as mainly colicky but at times sharp. The pain was neither relieved nor aggravated by food. About one hour after the onset of the pain the patient begins to vomit repeatedly. This also does not relieve her. An attack may come on at any time of day. After several days of pain and vomiting she will be free of symptoms for a few days and then another attack begins. When the pain is severe she feels like moving her bowels, but after one or two rather loose motions her efforts are futile. Her appetite is good but she has been losing weight steadily (32 pounds [14.5 Kg.] in the last six weeks) presumably due in part to her vomiting and fear of eating. There has been no melena or hematemesis, no jaundice or "indigestion." She avoids fatty foods somewhat. At times she complains of a feeling of "clogging up" in her neck, relieved by vomiting. This has been present for three months. Otherwise the history is irrelevant except that three years ago she had one of these attacks for a short time. Physical examination on three separate occasions showed generalized tenderness over the gallbladder region. Rectal examination was too painful to permit of any significant evidence being obtained. Vaginal examination revealed acute tenderness in the right fornix and slight tenderness in the left fornix. No masses were felt and the uterus presented no abnormality. The urine was normal on a number of occasions. The Wassermann test was negative. The red cell count was 4,800,000 and hemoglobin 86 per cent Sohli. The white count was 7,950 with polymorphonuclears 47 per cent, lymphocytes 27 per cent and eosinophils 26 per cent. This count has been confirmed in two different hospitals. Repeated examination of the stools for ova or parasites has been negative. Biopsy of a portion of the deltoid for cysts was also negative. Culture of the stools has been negative except for more or less fungus growth which seems to be either a manilia or a streptothrix. Gastrointestinal x-ray studies show considerable gastric retention after eight hours with no evidence whatever of ulcer or abnormality. There seems to be a severe ileitis. The temperature has been more or less normal throughout. X-ray examination of the chest is also negative. There are no complaints or observations referable to the other systems.

M.D., Vermont.

ANSWER.—It is most difficult to explain the eosinophilia in this case. The normal total white count with more than 2,000 eosinophils per cubic millimeter rather restricts the probabilities, but none of the probabilities suggested fit well into the clinical picture. In nearly every instance in which the white count is within normal limits and at the same time the total eosinophil count exceeds 2,000 (2,067 in the present case) the cause is likely to be trichinosis, arsenic poisoning, eosinophilic leukemia, dermatitis herpetiformis, periarteritis nodosa, Hodgkin's disease or lymphosarcoma. Only the first two are common causes.

The gastrointestinal symptoms, without positive observations, point to a functional origin. The gastric retention seems to

indicate pylorospasm. It seems likely that the "ileitis" may be bowel spasm. It would seem wise to investigate the function of the gallbladder, although the presence of gallbladder disease would not be likely to produce such a violent clinical picture.

If the diagnosis of functional gastrointestinal disorder is permitted, one must decide whether the underlying factors are psychic or allergic. An allergic cause would offer some explanation for the eosinophilia. Other well known allergic responses such as bronchial asthma and urticaria are associated with eosinophilia but rarely to such a degree.

In this case, then, the causes of eosinophilia should be carefully reviewed. The problem of trichinosis seems to have been adequately dealt with. Possible allergens, particularly drugs or foods, should be sought for to explain both the eosinophilia and the gastrointestinal symptoms.

EXPRESSION OF HUMAN BLOOD CONSTITUENTS

To the Editor:—In the last few years certain chemical substances, notably the serum chlorides and serum sodium as well as others, have been expressed in milliequivalents per liter rather than in milligrams per hundred cubic centimeters, which is the usual standard of measurement. This is rather confusing to clinicians, even those who have left medical schools recently. Could you please give me the normal ranges of the common chemicals such as sodium, potassium, chlorides and carbon dioxide expressed in milliequivalents per liter? Will you also kindly explain the reason for using milliequivalents rather than milligrams per hundred cubic centimeters in such cases?

M.D., New Jersey.

ANSWER.—The normal ranges of certain human blood constituents are as follows:

	Mg. per 100 Cc. in Serum	Milliequivalents per Liter of Serum	Millimols per Liter of Serum
Sodium.....	320-350	130-152	130-152
Potassium.....	16-22	4.1-5.6	4.1-5.6
Chloride.....	350-500	99-110	99-110
Calcium.....	9-11	4.5-5.5	2.25-2.75
Magnesium.....	2-3	1.0-2.5	0.8-1.25
Carbon dioxide, volumes %.....	50-60	44-52	23-26

The millimols per liter are calculated by dividing the milligrams per liter by the atomic weight of the element. The milliequivalents are the same as the millimols per liter in all cases in which the valence is 1, but if it is 2, as in the bivalent elements or radicals, the milliequivalents would, of course, be twice the millimol values. In the case of carbon dioxide the results are usually expressed as percentage by volume of carbon dioxide gas. In other words, 50 volumes per cent means that 1 liter of serum yields 500 cc. of carbon dioxide gas. Now 1 gram molecule of any gas under standard conditions is 22.4 liters, or 1 millimol is $\frac{1}{22,400}$ of that, or 22.4 cc. Hence 500 cc. of carbon dioxide would represent $\frac{500}{22.4}$, or 22 millimols. However, since carbon dioxide represents a bivalent acid, the milliequivalent value would be twice that, or 44 millimols. The advantage of the milliequivalent system is that calculation can be made easily in terms of one ion substituted for another or balancing another. Thus, 1 milliequivalent of any ion is always equivalent to any other milliequivalent of any other element or radical in balancing negative and positive ions or in substitution.

LESIONS OF TULAREMIA IN RABBITS

To the Editor:—Is it possible for one to tell on gross examination whether a rabbit has tularemia? Specifically, could a venter of meats tell by inspection of the dressed rabbit? Would the liver show any gross evidence? Or any other organ or part of the rabbit? Are domestic rabbits likely to have the disease or does it occur solely in wild rabbits?

M.D., California.

ANSWER.—Although ordinarily it is possible to tell on gross examination of the spleen or liver whether a rabbit has tularemia, in some instances the characteristic whitish pin head to match head size tubercle-like foci of necrosis may be so small as to be barely visible with the use of a hand lens; in rare instances such lesions may be completely invisible grossly. It would not be possible for a venter of meats to determine the presence or absence of tularemia by inspection of dressed rabbits, since there are no distinctive lesions in the muscles, fat or bones. *Pasteurella tularensis* (*Bacterium tularensis*) is, however, distributed throughout the muscle of infected animals and will survive several months of exposure to subfreezing temperatures. The typical lesions are to be found in the spleen, liver and lymph nodes. The disease does not occur in nature in domesticated rabbits; such rabbits are, however, susceptible to experimental production of the disease.

PNEUMONIA AND BRONCHIECTASIS—HAND DISABILITY FROM OLD BULLET WOUND

To the Editor:—A man aged 45, a veteran of the last war, presented himself for examination because of severe recurring bronchitis. He states that in 1916, after serving for two years, he developed bilateral pleurisy and pneumonia. Following recovery from this he found that every spring and fall he has attacks of bronchitis with expectoration of green sputum. Lately the condition has become more severe, and during any spell of damp weather he is subject to this distressing condition. In such a case could one assume that the pneumonia and pleurisy in 1916 have any bearing on the recurrent bronchitis? Prior to 1916 his physical condition was excellent. Secondly, in your opinion would such a person merit a pension? Furthermore, a bullet passed through the left forearm of the patient in 1918, since which date there have been attacks of intermittent swelling of the back of the left hand with numbness and stiffness of the little and ring fingers. Sensation is good throughout but muscle power is impaired. Can anything be done about this? The man is a farmer and because of these two conditions he is partially incapacitated.

Nathan Schechter, M.D., Ottawa, Ont.

ANSWER.—It is extremely difficult at this date to show a direct causal relationship between the bronchitis of today and the pneumonia of 1916 and it would seem equally difficult to prove that such a relationship did not exist. From the history it may be assumed that the patient has a bronchiectasis. Such a complication is not uncommon following influenzal pneumonia. Bronchiectasis is rare following pneumococcal pneumonia but it does occur. It is possible that an x-ray examination of the chest might be helpful but it is doubtful that even this will settle the question of causal relationship.

The only opinion of any value on the pension question is the opinion of the board that administers pension matters.

There can be no question of the service connection of the hand disability. Any improvement in this condition would be dependent on the present cause of disability. Is it a nerve injury or muscle injury? Is there mechanical circulatory obstruction due to contraction of scar tissue? When these points are determined, the advisability of a surgical attempt to correct the disability may also be determined.

IMMUNITY IN DIPHTHERIA

To the Editor:—May I have your opinion on the following statements: 1. "The immunity conferred by one attack of diphtheria is not of long duration, amounting probably to a few weeks or months only" (from Holt and Howland: Diseases of Infancy and Childhood, ed. 9, p. 851). 2. Toxin-antitoxin inoculations have been used in those found susceptible by the Schick test. Three injections are given at weekly intervals. The immunity may last for two years (from Osler and McCrae: The Principles and Practice of Medicine, ed. 9).

M.D., Arizona.

ANSWER.—1. In a large contagious disease hospital where approximately 20,000 cases of diphtheria have been treated over a period of years, second attacks of the disease have been witnessed hardly more than half a dozen times. Ordinarily it may be assumed that one attack of diphtheria does confer an immunity which is usually permanent.

2. Immunity established by the injection of three doses of toxin-antitoxin at weekly intervals is generally protective for a period of at least two years. At present three doses of plain toxoid or two doses of alum precipitated toxoid administered at intervals of from three to four weeks are preferred to toxin-antitoxin.

PLEURAL EFFUSION

To the Editor:—A pleural effusion (left side) following the course of high voltage roentgen treatment of a huge uterine fibroma developed the second week of irradiation. The following interpretations are possible: (1) a malignant growth with pleural or pulmonary metastases; (2) excessive irradiation; (3) an independent condition or disease, sui generis. Could you furnish information relative to the frequency of an afebrile pleural effusion encountered in the course of x-ray irradiation of the abdomen? Can carcinoma of the peritoneum or a sarcomatous degeneration of a uterine fibromyoma produce pleural effusion as the first manifestation of a generalized process?

M.D., New York.

ANSWER.—The pleural effusion is probably secondary to pleural or pulmonary metastases from a uterine sarcoma. Although there are references in the literature to pleural effusion secondary to roentgen treatment of the chest, this condition is extremely rare. Cases in which it is suspected nearly always prove to be caused by malignant growth. That an x-ray pleurisy should follow an irradiation of the abdomen is even more unlikely. The great majority of afebrile pleural effusions are cancerous in nature. Of course, there is a possibility that the pleural effusion is an independent disease in no way associated with the uterine enlargement. One can best answer this part of the query by quoting Richard Cabot, who always emphasized the fact that one disease was enough for a person to have at one time and that in the great majority of instances a single diagnosis would cover all signs and symptoms.

Additional information as to the actual nature of the effusion might be obtained by examining the pleural fluid for cancer cells, by injecting some into a guinea pig, and by removing the pleural fluid and then taking a roentgenogram of the lungs. This latter might reveal shadows suggesting either tuberculosis or a malignant condition. The absence of shadows does not rule out either disease.

TYPHOID IMMUNITY IN INFANT AND NURSING

To the Editor:—A patient developed typhoid between the third and fourth months of pregnancy. Subsequent to the delivery of an apparently healthy boy she was found to be a typhoid carrier. 1. Can the child have developed an immunity and, if not, at what age should typhoid immunization be started? 2. Is it safe to allow the baby to nurse?

D. M. Barringer, M.D., Lincoln, Ill.

ANSWER.—1. The child may have developed an immunity. Evidence for or against this fact might be obtained by actual tests of the child's antibody reactions as demonstrated by the ordinary Widal reaction. Another test using skin sensitivity has been suggested but is not in general clinical use. In this test local hypersusceptibility to typhoid bacillus protein is regarded as presumptive evidence of typhoid immunity.

2. If proper care of the nipples and ordinary cleanliness are employed, the child may be allowed to nurse. It is quite possible that the mother may cease being a carrier after a limited period. While about one third of recovered individuals are carriers for as long as three months, only 4 to 11 per cent, it is estimated, eliminate the bacilli indefinitely (more than three months) and so become classed as chronic carriers.

CONGENITAL HEMOLYTIC ANEMIA

To the Editor:—A primipara aged 28 who was given no antepartum care was delivered of a male baby by low forceps. An acute episode of congenital hemolytic anemia (jaundice) then developed. She had an enlarged spleen, severe microcytic normochromic anemia, a high white blood cell count and a continuous fever. In spite of daily pint blood transfusions after the fifth day, and later continuous blood transfusion, she died at the end of the tenth day. Twenty years previously she had had an attack similar to this which was relieved by transfusion. During the interim she had been in fairly good health. Splenectomy was planned for if the crisis was controlled. 1. What mechanism brings on these acute attacks when the patient is free from symptoms for years? 2. What possibility is there of this condition developing in the child? 3. What are the earliest signs or symptoms by which this condition may be detected in the child? 4. In Queries and Minor Notes for April 6 you say "splenectomy is indicated if acute attacks occur." What would have been the best method of controlling the phase in the case cited prior to splenectomy? 5. Is vitamin C of any value in these cases?

M.D., New York.

ANSWER.—1. The mechanism that brings on acute attacks in congenital hemolytic anemia is not understood. Such attacks may be spontaneous or precipitated.

2. In a family in which one of the parents is suffering from congenital hemolytic anemia an average of half of the children may be expected to be carriers of the disease.

3. The presence of the latent stage of congenital hemolytic anemia is characterized by increased fragility of the erythrocytes to hypotonic salt solution and by spherocytosis of the red cells. Spherocytosis is recognized by an increase in the volume-thickness index (Haden, *Am. J. M. Sc.* 188:441 [Oct.] 1934). Excessive hemolysis of the red cells is associated with anemia, reticulocytosis and jaundice.

4. There is no way to control an acute hemoclastic crisis except by blood transfusions and splenectomy. Doan, Curtis and Wiseman (*THE JOURNAL*, Nov. 16, 1935, p. 1567) consider emergency splenectomy a life saving procedure in such cases.

5. There is no evidence that vitamin C is of any value in cases of this sort.

FREQUENCY OF URINATION IN YOUNG GIRL

To the Editor:—The answer to the question "Frequency of Urination in Young Girl" (*The Journal*, June 22, 1940, p. 2491) does not specifically discuss the most likely diagnosis in this case, namely, chronic granular urethritis. Folsom (*ibid.*, Nov. 7, 1931, p. 1345), in his discussion of the glands of the female urethra, has pointed out that the characteristic inflammatory changes are by no means limited to adult women. Moore and I have published observations on the unsuspected common occurrence of granular urethritis in young girls characterized by disturbance of micturition with normal urine (Spence, H. M., and Moore, Halcutt: Female Urethra in Childhood, *Texas State J. Med.* 35:234 [July] 1939, and Spence, H. M.: Granular Urethritis in Women, *J. Urol.* 43:199 [Jan.] 1940). In the query the diurnal nature of the frequency and the absolutely normal urine would be more suggestive of urethral and not of tuberculous or a neurologic lesion. A urethroscopic examination with careful attention to the caliber of the urethra and search for the granular appearance of the mucosa and the presence of papillary or cystic masses is indicated. If the suspected lesion is found, simple urethral dilations will result in dramatic relief.

Harry M. Spence, M.D., Dallas, Texas.

Medical Examinations and Licensure

COMING EXAMINATIONS

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in *THE JOURNAL*, September 14, page 956.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Part II, Baltimore and New York during October and Boston during November. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Various centers. Feb. 20. Final date for filing application is December 21. *Oral*. Cleveland, May 31-June 1. Final date for filing application is April 1. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral*. Chicago, Dec. 6-7. Applications for Group A must be on file not later than Nov. 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Chicago, Oct. 18-19. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville, Ky.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Part I Group B examinations, locally, Jan. 4, 1941, at 2:00 P. M. Final date for filing application is Oct. 5. Part II, Groups A and B, Cleveland, Ohio, June 1941, immediately prior to opening of A. M. A. meeting. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Cleveland, Oct. 5. *Written*. Various centers, March 8. *The only written examination during 1941*. Applications must be on file not later than Dec. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Oral and written*. New Orleans, January 1941. Final date for filing application is November 15. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF PEDIATRICS: New York, March 30-31, following the Region I meeting of the American Academy of Pediatrics. Chicago, May 18, following the Region III meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: *Oral*. New York, December 18-19. Final date for filing application is October 8. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Boston, Sept. 26-29. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Oral and Written*. Chicago, February 1941. Applications must be on file not later than Oct. 15. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Wisconsin June Report

Dr. H. W. Shutter, secretary, Wisconsin State Board of Medical Examiners, reports the written and practical examination for medical licensure held at Milwaukee, June 25-27, 1940. The examination covered twenty subjects and included 100 questions. An average of 75 per cent was required to pass. Ninety-three candidates were examined, all of whom passed. Thirty-one physicians were licensed to practice medicine by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists	(1940)	80	
Loyola University School of Medicine	(1940)	85, 87	
Northwestern Univ. Medical School	(1940)	80, 82, 83, 84, 85, 86

Book Notices

Cancer: A Manual for Practitioners. The Committee on Publication (representing the Massachusetts Medical Society and the American Society for the Control of Cancer): George W. Holmes, Chairman, Ernest M. Daland, M.D., Shields Warren, M.D., and Channing C. Simmons, M.D., editor. Cloth. Pp. 254, with 2 portraits. Boston: Massachusetts Department of Public Health, Division of Adult Hygiene, 1940.

This compact little volume, published by a committee representing the Massachusetts Medical Society and the American Society for the Control of Cancer, is notable for its unusual purpose and content. Written expressly to present to the general practitioner a general survey of cancer together with information pertaining to the problem of early diagnosis and treatment, it serves also to stimulate an interest in the progress of cancer work and to point out the urgent need for an adequate program of control. It is of particular interest to practitioners in Massachusetts, since there is included an outline of the Massachusetts cancer program and a survey of the various facilities for diagnosis, therapy and research. In addition, distribution of this volume to practitioners of Massachusetts is made possible by funds obtained from the U. S. Public Health Service and by the Massachusetts branch of the Women's Field Army of the American Society for the Control of Cancer. The material shows careful arrangement and is commendable for its clarity and brevity. Each chapter is contributed by an individual particularly interested in the subject for review. The broad aspects of cancer are presented in the introductory chapters, which include a historical survey, an analysis of the epidemiologic aspects of cancer and a description of the principles of therapeutic procedures employed at the present time. The chapters which follow are devoted to the various types of cancer—classification being based on the site of origin of the lesion (cancer of the lip, cancer of the breast, cancer of the ovary). The leukemias, Hodgkin's disease and allied disorders also are considered. The chapters are short and convey the essentials of the subject under discussion. Since exhaustive dissertation is not within the scope of this book, it would be necessary to consult more complete textbooks for detailed information. The character of the book hardly permits review of various controversial opinions and ideas, although in some instances individual inclinations are reflected. On the whole, the material is adequately and conservatively treated. Valuable additional chapters for the practitioner contain suggestions for lay talks on cancer and an explanation of the purpose and results of activities for the control of cancer. The committee for publication has prepared a well integrated, practical manual which augments the educational features of any cancer control program.

Rural Health Work in Hungary. By Dr. B. Johan, Undersecretary of State. Publications of the State Hygiene Institute of Hungary, No. 9. Paper. Pp. 230, with 118 illustrations. Budapest, 1939.

Twelve years ago a complete system of medical care, both preventive and curative, was established for the rural areas in Hungary. This health organization centers around the State Institute of Hygiene, the establishment of which was prompted by grants from the Rockefeller Foundation, and through this institute official control has been provided for the preventive health services and for affiliation with the Green Cross Service, which corresponds to the American plan for public health nursing. Hungary has been divided into twenty-six districts, each with its chief health officer. Only physicians who have served as local health officers for not less than five years are eligible to this appointment. In 1938 there were 190 local health officers in Hungary who prior to such appointment must serve an apprenticeship as a community or village physician and must have passed the final examinations subsequent to taking a nine months special course for health officers. The actual health work in the villages is carried on by the village physicians, of whom in 1939 there were 1,193, an average of one for each 4,900 of the population. The duties of the village physicians include the practice of curative medicine and responsibility for the public health activities of the community. They are charged with the execution of measures to prevent the spread of communicable disease, control the water and food supply, supervise the health of children at school, issue certificates of death, participate in necropsies and direct and supervise the public health activities. The success of the program of health education depends largely on the ability of the village physician and the public health nurse. Health centers have been established in the rural areas where both curative and preventive services are provided. The author provides many interesting graphs and statistical tables portraying the rise and fall of disease in different parts of Hungary, especially in relation to the intensiveness of health education. There are included in this monograph plans of health centers and reproductions of posters used in the program of propaganda.

A Textbook of Surgery. By John Homans, M.D., Clinical Professor of Surgery. Compiled from Lectures and Other Writings of Members of the Surgical Department of The Harvard Medical School. With a Special Bibliographical Index. Fifth edition. Cloth. Price, \$8. Pp. 1,272, with 530 illustrations by Willard C. Shepard. Springfield, Illinois & Baltimore: Charles C. Thomas, 1940.

This has been revised and brought down to date in many particulars. General surgical subjects such as repair of wounds, surgical bacteriology, technic, suppuration, trauma and specific diseases are discussed first. To each chapter there is attached a historical prologue which is both interesting and instructive. These historical sketches aid greatly in the proper introduction of the student to surgery. The anatomy of the locale under discussion is well described and frequently clarified by a simple line sketch. Diagnosis of surgical diseases together with etiology and pathology is treated in a thorough and scholarly manner. There is a trace of pedantism, as evidenced by a tendency to involved sentence structure and a rather stilted style of writing. In many portions, however, the flow of words is free and easy and is pleasantly received by the medical student. The greater portion of the book deals with specific surgical problems of the various bodily systems. One of the most excellent sections concerns thoracic surgery. The problem of empyema and pulmonary infection is discussed. The importance of postoperative pulmonary complications cannot be overemphasized as a cause of morbidity. These subjects are fully presented and represent a valuable educational source. Heparin is mentioned as a means of treatment of pulmonary embolism, indicating the authors' ability to keep this textbook completely modern. The chapters on neurosurgery, inspired as they were by Cushing, deserve mention. Anesthesia is another subject presented in a clear and scientific manner. As a textbook for general use by medical students, this volume is not surpassed by any other. The illustrations are usually graphic but, nevertheless, simple. A few illustrations are not well chosen. The pictures of basal and squamous cell carcinoma on page 197, for example, represent advanced stages of these diseases. They are likely to be misleading in that it is rare for the contemporary physician to see

these diseases in such advanced stages. Such drawings have little place in the modern textbook, in which early diagnosis and treatment should be stressed. The general competence of the book is well exemplified by the large bibliographic index and the numerous references. Successful revision enables this book to continue as a useful teaching tool.

Traité d'ophtalmologie. Publié sous les auspices de la Société française d'ophtalmologie. Par MM. P. Baillart, Ch. Coutela, E. Redslob, E. Velter. René Onfray: Secrétaire général. Tome VII: Neurologie (Fin): Chirurgie. Par MM. J. Bruneau et al. Cloth. Price, \$10.50. Pp. 931, with 414 illustrations. Paris: Masson & Cie, 1939.

The seventh of this eight volume system appeared on schedule and properly resembles its predecessors in clothing and character. The first third of the volume is devoted to the concluding phases of ocular neurology with the following subdivisions: peripheral and central disturbances of the oculomotor apparatus by Velter of Paris, strabismus by Onfray of Paris, nystagmus by Coppez of Brussels, ocular disturbances of trigeminal origin by Cerise and Thurel of Paris, semeiology of ocular troubles in disturbances of the central nervous system by Velter of Paris, neurosurgical diagnosis of disturbances in the region of the chiasm by Vincent and Puech of Paris, and intracranial hypertension and cerebral tumors by Martel and Guillaume of Strasbourg. These chapters vary considerably, as is to be expected from a mélange of authors, but on the whole are well written and clear in context and contain some excellent illustrations.

The second two thirds of the volume is devoted to ocular surgery, divided as follows: surgical generalities by de Saint-Martin of Toulouse, the lids and conjunctiva by Duverger and Velter of Limoges and Paris, the lacrimal apparatus by Merigot de Treigny of Paris, the cornea, sclera and iris by Duverger and Velter, extracapsular extraction of cataract by Van Lint of Brussels, intracapsular extraction of cataract by de Saint-Martin of Toulouse, luxation of the lens by de Saint-Martin, detachment of the retina by Veil and Dollfuss of Paris, anti-glaucomatous operations by Duverger and Veil, strabismus by de Saint-Martin and Onfray, enucleation by Carloti of Nice, the orbit by Terrien of Paris, foreign bodies in the eye and orbit by Duverger and Velter, and prostheses by Bruneau and Charpentier of Paris. That is an enormous amount of surgery to try to compress into 530 none too large pages, especially when the descriptions are supposed to be encyclopedic in extent. This is probably the most spotty part of the entire system. Much of it is good, although too abbreviated, but some unfortunately falls below textbook level. However, the illustrations are excellent, especially those in the chapters by Duverger and Velter. The bibliography is rather weak and only too often purely Gallic in character. The book making and general ensemble are up to the standards set in the previous volumes.

Your Allergy and What to Do About It. By Milton B. Cohen, M.D., and June B. Cohen. Cloth. Price, \$1.50. Pp. 177, with illustrations. Philadelphia, New York & London: J. B. Lippincott Company, 1940.

This book is written for the patient. Allergy holds a prominent position in the public eye and it requires more than a brief article to answer such questions as How are my symptoms produced? Can my allergy be cured? Hence this book. The authors' approach to the subject is biographic. Allergy has molded the lives of some famous men. Marcel Proust locked himself into a room where he could be relieved of asthmatic attacks and to amuse himself wrote several volumes that are classics. General William T. Sherman was comfortable when in the field but at home suffered from allergic attacks; he was sensitive to house dust. The French physician Charli's Richet sailed on the yacht of the Prince of Morocco to experiment with the poisonous proteins of the sea anemone. His experimental animals remained healthy after the first injection of the protein, but a few minutes after the second injection one of them suddenly died. Richet inoculated a second experimental animal with egg albumin and it died after the second injection. Thus the dose which, according to the principle established by Pasteur in his experiments with rabies, should have protected the animals from harm had so changed their bodies as to remove protection altogether. Physicians then began to wonder about some of their patients who became ill a few days after injection

of diphtheria antitoxin; they saw some relation between this and the startling results of Richet's experiments. In a few years medical men began to relate such strange diseases as hay fever and asthma to anaphylaxis and at last bound together many strange complaints under the term "allergy" or altered reactivity. In their small book the authors explain how the symptoms of allergy are produced and how the diagnosis is made. Special attention is given to hay fever, asthma, eczema, allergic rhinitis and hives. The problem of treatment of allergic diseases as well as details of the pathogenesis are not well understood. Perhaps these problems may be solved from some physical or chemical discovery by workers in fields apparently remote from medicine but still pertaining to the workings of the living cell. Thus our understanding of allergy may be entirely changed and the appearance of the allergic state may become no more than an occasional curiosity. The family of allergic diseases may then become merely an interesting episode in medical history.

Complete Guide for the Deafened. By A. F. Nlemoetter, A.B., M.A., B.S. With a foreword by Harold Hays, M.D., F.A.C.S. Cloth. Price, \$3. Pp. 256, with one illustration. New York: Harvest House, 1940.

The number of people in the United States who suffer from impaired hearing has been variously estimated at from ten to seventeen million. Like many other statistical figures, this is probably inaccurate, for no one can ever know even the approximate number. However, those afflicted are doubtless in need of some such book as this, since they so often seem to be hopelessly engulfed in their wretched state and know not how to orientate themselves. While not "complete," these seventy-seven chapters consider the origin and kinds of hearing defects, the influence of heredity, drugs, disease, old age, and mental attitudes, reeducation, employment, recreation, legislation, social considerations, personal adjustments, and hearing aids. An effort is made to overcome the so-called social stigma, the tendency to withdraw from one's fellows and the all important element of maladjustment. Advice is given to parents as to their attitude toward deafened children, how they can enjoy the radio, movies, sermons, public lectures, music, conversation with friends and the telephone. In such a small volume it is impossible, of course, to do more than touch on many phases of this problem, but the author has succeeded in covering much ground, and he attempts to lead the deafened to a richer, fuller life. Fraudulent and harmful aids and devices such as "ear oil" are explained and condemned in an effort to spare the victims agony of mind and spirit and depletion of purse. The author's style is fluent and conversational, which makes for easy reading. From a medical point of view the facts are accurate in the main, and no attempt has been made to overeducate the reader.

Le guide thérapeutique du médecin praticien. Par Jean Trabaud, professeur de clinique médicale, et J. R. Trabaud. Tome I: Les infections et les intoxications endogènes et exogènes. Tome II: Les maladies de l'appareil respiratoire. Tome III: Les maladies du tube digestif et de ses annexes. Tome IV: Les maladies des appareils cardio-vasculaire et urinaire. Les maladies du sang. Tome V: Les maladies nerveuses et mentales. Préface de M. le Professeur Tanon. Papier. Price, Tome I, 55 francs; Tome II, 43 francs; Tome III, 48 francs. Pp. 288; 210; 243; 284; 253. Paris: Vigot Frères, 1940.

The task the authors have set themselves is a pretentious one indeed; namely, to encompass the entire field of therapeutics in a manual consisting of eight small format volumes, viz. (1) infections and intoxications; (2) diseases of the respiratory organs; (3) diseases of the digestive tract; (4) cardiovascular and urinary diseases; (5) nervous and mental diseases; (6) diseases of children; (7) eye, ear, nose and throat diseases, and (8) genito-urinary and cutaneous diseases. The last three still await publication. A concise description of symptomatology of each disease is followed by recommendation of a suitable dietary regimen, hygienic measures, general and local treatment, including physical therapy, irradiation and spas; prescriptions follow. As the authors claim that the majority of patients prefer proprietary medicines to officinal preparations, the first group dominates the picture. As to the spas, only French watering resorts are mentioned. A cursory perusal of the five volumes has disclosed several omissions, for instance the use of sulfanilamide in the treatment of gonorrheal arthritis or of thiamine, pituitary or x-rays in the treatment of herpes zoster. Not less than thirty-five pages is allotted to prescriptions for various types

and phases of tuberculosis. There are many therapeutic suggestions which do not coincide with generally accepted points of view in this country. As countless French proprietary drugs are specified and only French resorts are recommended for balneologic treatment, the work may be fitted to the needs of French colleagues but cannot be recommended for practical use by American physicians.

Illustrative Electrocardiography. By Julius Burstein, A.B., M.D., Associate Electrocardiographer and Chief of the Cardiac Clinic, Morrisania City Hospital, New York. Originally written by the late Joseph H. Bainton, A.B., M.D., and Julius Burstein, A.B., M.D. Second edition. Cloth. Price, \$5. Pp. 292, with 106 illustrations. New York & London: D. Appleton-Century, Incorporated, 1940.

This edition, like the preceding one, is based on a description of illustrative electrocardiograms. In this edition the author has added the subject of chest leads and included a verbatim copy of the report of the American Heart Association Committee on precordial leads. The method of presenting the electrocardiograms is commendable, and it is regrettable that a large number of errors nullify its usefulness. The following are some of the typical errors:

Plate 17 shows a sinus arrhythmia with nodal escape and dissociation and not a wandering pacemaker. It is questionable whether the attempt to locate the origin of the premature systole as stated on page 49 is correct. In plate 20 the author mistakes a sinus P wave occurring at the proper time for a premature P wave. In plate 21 the author overlooks a pulsus trigeminus. In plate 22 the author fails to draw attention to the effects of the premature systole on the contour of the succeeding beat. In plate 26 the author fails to recognize that the first premature complex is a fusion beat. In plate 27 the author labels P waves without evidence for doing so. The curves in plates 27 and 28 should better have been called supraventricular tachycardia. The diagnosis in plate 30 is problematic, and it would have been better to leave this illustration out. The author should have pointed out in plate 31 that, in addition to the short paroxysms, there are single premature ventricular extrasystoles. In plate 33 the author should have labeled the auricular waves as F instead of P waves. Plate 37 would be considered impure flutter. In plate 40 the author overlooks premature systoles in leads 1 and 3. It is doubtful whether the slight variation in the PR interval in plate 44 is worth mentioning. Plate 47 is complex and might have been left out, and in lead I are two instances in which there is 1:1 conduction. In plates 48, 87 and 88 the presence of intraventricular block might be questioned. Plate 49 is misdiagnosed; it is an instance of second degree auriculo-ventricular block with a Wenckebach phenomenon and with nodal escapes (the second and sixth complexes). The subject of T wave abnormalities on pages 134 and 135 is poorly presented; the author does not distinguish between the S-T segment and the T wave; the idea that T wave size is related to vigor of the heart is erroneous. The interpretation of plate 54 is wrong. There is no reason to suspect a myocardial infarct in plate 56. The prolonged duration of QRS in plate 57 is overlooked. The statement that the high voltage in plate 65 indicates a good myocardial vigor is without foundation. This is true also of the statement regarding QRS in plate 66 A. In plate 74 the term "old coronary occlusion" is a bad one. Plate 75 shows a partial auriculoventricular block with a Wenckebach phenomenon and not a complete auriculoventricular block. In plate 77 the so-called premature contraction in lead I is an extracardiac artefact. In plate 79 all the premature systoles are auricular in origin. The author overlooks the fact in plate 82 that many of the premature extrasystoles are blocked, giving rise to the pauses. In plate 84 the pauses identified as sino-auricular block are really due to blocked auricular premature systoles. Plate 89, when handled to conform with the normal electrocardiogram, shows left ventricular preponderance. The P wave changes of the dominant beats in plate 91 are due to the effect of the auricular premature systoles. Plate 92 A is probably an instance of complete auriculoventricular dissociation. No useful purpose is served in showing the original lead 4 in plate 96, since this lead is no longer utilized.

Further, a number of the illustrations are complex. Considering the handling by the author, they could have been

omitted. Attention is drawn to the foregoing errors in order to demonstrate the need of care in the presentation of such electrocardiograms for the use of physicians. A great deal of harm in educating the ordinary reader can be done by loose writing and by erroneous concepts which serious students in the field would not make. Because of these circumstances, and despite the excellence of the reproductions, this book cannot be recommended.

Biochemistry of Disease. By Meyer Bodansky, Ph.D., M.D., Director of the John Sealy Memorial Laboratory and Professor of Pathological Chemistry, University of Texas School of Medicine, Galveston, and Oscar Bodansky, Ph.D., M.D., Lecturer in Biochemistry, Graduate Division, Brooklyn College, New York. Cloth. Price, \$8. Pp. 684, with 72 illustrations. New York: Macmillan Company, 1940.

The tremendous strides made in recent years in the development of scientific medicine are reflected in this book. It is apparent that the rapid progress has depended to a great extent on the more complex biochemical studies and that a sound knowledge of this phase of medicine is essential for further elucidation of disease and its treatment.

This book is apparently not intended to be a textbook of clinical biochemistry but rather a critical review of the investigational work in this field. Much of the investigational work presented in this volume is still controversial and the authors have wisely refrained from making their statements dogmatic and conclusive although it is possible that some readers would desire more definite statements. The evaluation of the data in this book is uniformly sound. The scope of the book is wide and the enormous amount of information is presented in a clear, concise and logical manner. Obviously the authors could not go into great detail on many of the subjects, but readers may easily follow their interest in any subject through the use of the ample bibliography. Each chapter starts with a brief but concentrated discussion of the normal biochemical relationships of the particular subject in view. Then with each subdivision there is another brief introduction of the fundamental concepts before the conditions found in disease are presented. In this way the reader's memory is constantly refreshed and his understanding of the subject matter improved. There are included in the book discussions on subjects which have been recently expanded and which are of the utmost importance in modern medicine. These chapters are on the biochemical aspects of the endocrines, vitamins, problems of gynecology and obstetrics, and neurologic and psychiatric disorders. These features will be greatly appreciated by physicians and students because of the widespread interest in these subjects and their growing importance in medicine.

While this book is not a reference work for physicians to use in administering practical therapy or a course in laboratory technic for the diagnosis of disease, it is an excellent means by which the modern physician may keep abreast of the scientific developments in disease, which might be quite impossible if the data were to be obtained directly from the literature.

Liquor: The Servant of Man. By Walton Hall Smith and Ferdinand C. Heilwig, M.D. Cloth. Price, \$2. Pp. 273. Boston: Little, Brown & Company, 1939.

In this book there is an attempt to make an unbiased and scientific survey of the real effects of alcohol on the human system. The authors believe that the facts concerning alcohol have been buried under a haze of misconception. The history of drinking, the physiologic effects of alcohol and the relation between alcohol and disease are discussed. Some information concerning the psychology of drinking is included. Startling are some of the statements which are made:

There has been found no evidence that prolonged and copious use of alcohol causes any disease.

It is the present opinion of many authorities that, instead of causing arteriosclerosis, alcohol can act to retard it.

The statement is also made that alcohol is an active ingredient in all intoxicants and that its toxicity is increased and not decreased by aging or by congeners or substances mixed with it to make it more palatable. The book is written for the average person and not for the problem drinker. The average individual will find much of interest in it.

Poisons: Their Isolation and Identification. By Frank Bamford, B.Sc. With a foreword by Professor Sydney Smith, M.D., F.R.C.P., Regius Professor of Forensic Medicine, University of Edinburgh, Edinburgh. Cloth. Price, \$4. Pp. 344, with 21 illustrations. Philadelphia: Blakiston Company, 1940.

Here is a book that should be well received by the chemist who is occasionally called on to do the kind of work indicated by the title. Written by a man who was intimately acquainted with the problems that confront the chemist in medicolegal laboratories, the many methods and tests must have been subjected to practical laboratory trials. To the toxicologist it will be useful as a compact and systematic arrangement of the more important poisons with which he may come in contact. The chapter on the isolation and identification of alkaloids is especially good. The many tests that depend on color reactions are open to criticism. In the minds of many, the best that can be said for such tests is that they are indicative. Microchemical tests, especially descriptions of crystals obtained by microsublimation, could have been given more attention. Photomicrographs, though space consuming, would have been of assistance to the chemist not actively engaged in this kind of work.

Chemotherapy and Serum Therapy of Pneumonia. By Frederick T. Lord, M.D., Member of the Board of Consultation, Massachusetts General Hospital, Boston, Elliott S. Robinson, M.D., Ph.D., Director, Division of Biologic Laboratories, Massachusetts Department of Public Health, and Roderick Heffron, M.D., Medical Associate, The Commonwealth Fund, New York. Cloth. Price, \$1. Pp. 174, with 9 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1940.

This small volume, simply and interestingly written, with an eye to detail, is a mine of information which summarizes present opinions concerning the best methods to be employed in the treatment of lobar pneumonia. In addition it gives adequate brief summaries of existing knowledge concerning the etiology, epidemiology, diagnosis and past and present views on the prognosis of lobar pneumonia. It is the opinion of the reviewer that the authors have presented the respective merits of anti-pneumococcus serum or sulfapyridine in a critical and fair manner. While he might argue with the authors over the proposed criteria which are set up as indications for combined serum and chemotherapy, he believes that this is one of the books that should have a place on every physician's desk.

Mammalian Genetics. By William E. Castle, Research Associate in Genetics, University of California, Berkeley. Cloth. Price, \$2. Pp. 169, with 131 illustrations. Cambridge: Harvard University Press, 1940.

In this small book Professor Castle, who was a pioneer and is a recognized authority in the field of mammalian genetics, has summarized what is known about the inheritance of characters in laboratory and domestic mammals. Especially interesting is a table of comparative gene mutations found in the rabbit, house mouse, Norway rat, black rat, field mouse and guinea pig. His discussions of sex differentiation and sex determination are brief but they are good summaries of what is known about these topics. In his chapter on maternal inheritance he takes to task those who would attribute all inheritance to the genes. There is only an occasional reference to the genetics of human characters. The book is highly recommended to those who do not have the time to read the detailed papers in this important field. To those working in the field it is a welcome summary and synthesis.

Asthma and the General Practitioner. By James Adam, M.A., M.D., Surgeon-in-Charge, Asthma Clinic, Stobhill Hospital, Glasgow. With foreword by James Biddle, M.D. Cloth. Price, \$2. Pp. 137. Baltimore: William Wood & Company, 1939.

One can briefly summarize the good points of this book by saying that the author insists that the asthmatic patient be given a complete medical workup and should not be looked on as only a problem in allergy but a real medical problem, taxing the ingenuity of even the most facile mind. However, what the author apparently believes are newly discovered truths have been known and practiced by American physicians for years in the treatment of asthma. Many dogmatic positive statements are made which are not supported by scientific observation or laboratory investigations. It is insufficient to become emotionally aroused about a method of treatment without adding scientific proof.

Annual Report for the Year 1939, Central Narcotics Intelligence Bureau, Egyptian Government. Paper. Pp. 185, with illustrations. Bulag, Cairo: Government Press, 1940.

The Annual Report of the Central Narcotics Intelligence Bureau for 1939 contains numerous interesting accounts of investigations by which the Intelligence Bureau has been able to seize purveyors of narcotics in Egypt, the narcotics being principally hashish and opium. There are specific reports of cases in which three doctors and two chemists were concerned with the sale of narcotics. Most interesting was the discovery of a great amount of opium smuggled into Egypt in the stomach of camels, the opium being kept in a zinc container which the camel swallowed. It has been determined that it will be necessary to install x-ray equipment in the custom station through which 30,000 camels pass each year in order to make a routine study of a certain percentage of the camels in order to detect the presence of opium.

Your Child's Development and Guidance Told in Pictures. By Lois Hayden Meek, Ph.D. Cloth. Price, \$2. Pp. 166, with 163 illustrations by Lucia Manley. Philadelphia, New York, Toronto & London: J. B. Lippincott Company, 1940.

This picture book for parents portrays and discusses the life of children from 1 to 6 years old. Growth, daily routine, eating, elimination, relations with family and other children, training, fear and illness are all discussed. However, a chapter on play is omitted and, according to the author, is being reserved for a book of its own. Proper methods, pitfalls and problems are portrayed from which the parent is to take only what concerns his particular child. Thus this book demonstrates that children of the same age are not all alike and that most children are capable of doing a number of things for themselves and of performing physical feats parents do not often credit them with the ability to do. Because the text which accompanies these excellent pictures, drawings and charts is poorly written, reading and comprehension is often difficult. However, the material presented is sound, and the author also includes her references and a list of other books for parents.

A Textbook of Histology. By Harvey Ernest Jordan, A.M., Ph.D. Professor of Anatomy and Director of the Anatomical Laboratories, University of Virginia, Charlottesville. Eighth edition. Cloth. Price, \$7. Pp. 690, with 609 illustrations. New York & London: D. Appleton-Century Company, Inc., 1940

The general plan of this book remains unchanged; the author has, however, incorporated important additions to the subject as recorded in the recent literature, as well as many new illustrations. Experience has shown that teachers of histology prefer to use their own laboratory outlines. The author has therefore eliminated the chapters on directions for laboratory work and on histologic technic, which is taken up in detail in many special books on technical methods. References to the literature are recorded as footnotes and reassembled in a bibliography at the end of the book, thus making it convenient for the student who desires to pursue further the study of particular subjects. The numerous illustrations are well adapted to the text and some of them are in color.

Practical Dietetics With Reference to Diet in Health and Disease. By Alida Frances Patee. Twenty-second edition. Cloth. Price, \$3. Pp. 868, with illustrations. Mount Vernon, N. Y.: The Author, 1940.

What foods are most effective in increasing hemoglobin? What foods supply potassium? This book answers these and many other questions in its tables, which list foods under such headings in the order of their importance. Indeed, an extensive appendix is composed entirely of tables of food values, including those which are rich in minerals, tables listing foods which are highest in cellulose, highest in cholesterol, foods that will produce flatulence, foods which contain nicotinic acid, foods which are acid forming and foods which contain the various vitamins. Diet therapy is discussed by specialists who go into great detail about the dietetic treatment of diabetes mellitus, arthritis and gout, obesity, emaciation, Addison's disease, tuberculosis, constipation, nephritis, the anemias, heart disease, pregnancy, typhoid and infant feeding. Among the details on the preparation of foods for both the sick and the well person, it is shown how to prepare salads, cook vegetables and make different kinds of bread, soups and other dietary products. This

book is a storehouse of information. The arrangement, as in previous editions, follows the "Curriculum Guide for Schools of Nursing" issued by the National League of Nursing Education. Parts of this edition have been entirely rewritten.

Let's Talk About Your Baby. By H. Kent Tenney, Jr., M.D., F.A.A.P., Associate Professor of Pediatrics, University of Wisconsin Medical School, Madison. With a foreword by Dr. Joseph Brenemann, Chief of Staff, Children's Memorial Hospital, Chicago. Second edition. Cloth. Price, \$1. Pp. 115, with illustrations. Minneapolis: University of Minnesota Press, 1940.

The first edition of this book was published privately by Dr. Tenney for his patients. Written in the conversational manner, it covers the subjects of furniture, clothing, feeding, training and health for the baby's first year as well as most of the relatively unimportant things which worry many mothers. The baby's point of view, a common sense attitude and the availability of the doctor are all stressed. The manner of presentation and the large amount of information included make this book enjoyable and valuable reading. It is, indeed, a perfect book for parents.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Evidence: Osteopath as Expert Witness in Malpractice Suit Against Physician.—The plaintiff on March 3, 1936, was struck on his head by a falling tile. He was taken to the defendant physician, who examined him and, finding no objective evidence of injury, gave him some medicine and told him not to go back to work until he felt better. Soon thereafter he commenced to suffer pain in his head, accompanied by nausea and dizziness. He returned to work the next day but on the day thereafter his pain increased and he again visited the defendant, who gave him some liniment and advised him not to work until the next week. After attempting unsuccessfully to work the following week he again returned to the defendant, who took his blood pressure and found it above normal. At the time of his next visit to the defendant, after working for one week on the latter's advice, his blood pressure was higher. On the request of the plaintiff's wife that a roentgenogram be taken of the plaintiff's head the defendant caused such to be made, but what it disclosed does not appear in the published report. The plaintiff was hospitalized for thirteen days during which time two lumbar punctures were performed on him by the defendant. Later he brought suit against the physician for malpractice, alleging that he had sustained permanent injuries as the result of the defendant's negligence in failing to take roentgenograms promptly, in failing to diagnose correctly his injury as one of skull fracture and in failing to apply the usual and recognized treatment for skull fracture, namely, immobilization in bed with ice packs to the head and heat to the feet, and for the cerebral hemorrhage which developed. The trial court directed a verdict for the defendant and from a judgment thereon the plaintiff appealed to the court of appeals of Ohio, Lorain County.

At the trial the plaintiff endeavored to establish negligent conduct on the part of the defendant by offering the testimony of two osteopaths as expert witnesses as to the treatment which they would have rendered to the plaintiff if they had been called to treat him. However, on the motion of the defendant, the trial court withdrew this testimony from the consideration of the jury because the testimony of the osteopaths did not indicate that they possessed any knowledge whatever as to the standard of skill, care and diligence ordinarily exercised by practitioners of medicine and surgery. The action of the trial court met with the full approval of the court of appeals. In malpractice actions, said the court, the care, skill and diligence exercised by the defendant is to be judged by that standard of care which ordinarily is exercised by physicians and surgeons of the same school of medi-

cine in the same or similar communities. The court relied for its decision on 21 R. C. L. 383, section 28, which states:

In an action for malpractice a physician or surgeon is entitled to have his treatment of his patient tested by the rules and principles of the school of medicine to which he belongs, and not by those of some other school, because a person professing to follow one system or school of medicine cannot be expected by his employer to practice any other, and if he performs the treatment with ordinary skill and care in accordance with his system, he is not answerable for bad results.

Recognizing the fact that the injury which the plaintiff claimed he had sustained was of such a nature as not to be understood by lay witnesses but required a high degree of expertness for its diagnosis and treatment, the court could find in the record no evidence from which the jury could determine the standard of care, skill and diligence by which the defendant physician's conduct was to be judged. Furthermore, the trial court properly refused to allow the plaintiff to call the defendant as an adversary party for the purpose of cross examining him to establish the standard of care, skill and diligence by which the defendant's conduct should be judged and then by further cross examination to establish that the acts of the defendant complained of were negligent. In the judgment of the court, the plaintiff had even failed to present credible evidence that he had sustained a skull fracture.

Accordingly, the court of appeals held that the trial court had properly directed a verdict for the physician and so it affirmed the judgment in his favor.—*Forthofer v. Arnold (Ohio)*, 21 N. E. (2d) 869.

Medical Practice Acts: Surgical Diathermy by Naturopath Constitutes Unlawful Practice of Medicine.—The defendant, a licensed naturopath, removed "a lump or growth," which he diagnosed as "cancer," from the bottom of Mrs. Larkin's right foot by cauterization with "a surgical diathermy" apparatus, an apparatus commonly used by surgeons. According to the defendant, "electricity . . . was turned on the target [presumably the growth on the patient's foot] through a copper wire connected with a diathermy machine and from one-half to an inch from the target" and the heat emanating therefrom on "the target" produced a burn about 1 inch (2.5 cm.) in diameter and about one-eighth inch (0.32 cm.) deep, which destroyed the growth. For the performance of this procedure the naturopath was convicted of practicing medicine without a license, in violation of the Arizona medical practice act, and was sentenced to the penitentiary. He then appealed to the Supreme Court of Arizona.

The naturopath contended that it is not a statutory offense in Arizona to practice medicine and surgery without a license so to do. Since every one at common law, he argued, could practice medicine or the healing art, it is not a crime so to practice without a license unless some particular statutory provision makes it so. The section of the Arizona medical practice act pertinent to this matter merely provides: "Any person who practices, or attempts to practice, without having a valid, recorded certificate, shall be guilty of a felony . . ." (Revised Code, 1928, section 2560, as amended, Laws, 1935, chapter 99, section 2). This, the naturopath contended, is inadequate to make it a statutory offense to practice medicine and surgery without a license. The Supreme Court, however, held that the provision in question did make it a statutory offense to practice medicine and surgery without a license. This provision is a part of a section of the medical practice act and, in the Revised Code, 1928, it appears under the title "Medicine and Surgery." Provisions corresponding to this particular section appeared in the Revised Statutes, 1913, under the title "Practice of Medicine" and expressly made it a misdemeanor for any person to practice "medicine or surgery" without being licensed so to do. The Revised Code, 1928, said the court, was the result of studies made by a code commissioner whom the legislature prior to 1928 directed to codify the then existing laws and expressly instructed not to make any change in existing laws, but only to harmonize where necessary, reduce in language and remove inconsistencies (Laws, 1925, chapter 35, section 3). The court, concluded therefore, that the omission of the words "medicine and surgery" following the prohibition against unlicensed practice in the section in question had been done merely to eliminate redundancy of language. The effect of the omission was not to exempt one from punishment who practices medicine without a license.

The court was next called on to determine whether or not the acts of the naturopath were within the scope of the license to practice naturopathy which he possessed. In the practice of naturopathy in Arizona, said the court, no medicine may be used and the treatment must be nonsurgical. The naturopathic practice act of Arizona (Laws, 1935, chapter 105) authorizes persons possessing the qualifications therein prescribed, when duly licensed by the board of naturopathic examiners, to practice naturopathy. Section 5 of that act reads:

Naturopathy Defined. For the purpose of this Act, Naturopathy, which includes all forms of physiotherapy, is hereby defined to be: A system of treating the abnormalities of the human mind and body by the use of drugless and nonsurgical methods, and includes the use of physical, electrical, hygienic, and sanitary measures incident thereto.

This section permits a naturopath to use electricity in treating the human body and mind but prohibits him from performing surgical operations. His methods must be nonsurgical and drugless. The operation performed by the defendant was with an instrumentality in use by surgeons, and so it was conclusively surgical in its nature. If the defendant had used a scalpel to cut out the growth instead of burning it out, the act would have been no more surgical. While he had the right to use electrical heat in the practice of naturopathy, he had no right to use it to perform a surgical operation. There was nothing in the evidence to indicate that the defendant carelessly or mistakenly administered an overdose of heat or that he burned his patient by accident. On the contrary, the evidence showed that he intentionally and purposely applied the electricity to destroy the lump on the patient's foot by burning it out. He adopted the surgeon's method of curing cancer, the only one, said the court, that has been discovered to date.

For the reasons stated above, the judgment of conviction was affirmed.—*Nethken v. State (Ariz.)*, 104 P. (2d) 159.

Society Proceedings

COMING MEETINGS

- American Academy of Ophthalmology and Oto-Laryngology, Cleveland, Oct. 6-10. Dr. William P. Wherry, 107 South 17th St., Omaha, Secretary.
- American Association of Obstetricians, Gynecologists and Abdominal Surg., 26-28. Dr. James R. Bloss, 418 Secretary.
- Ar Association, White Sulphur Springs, M. Rackemann, 263 Beacon St., Boston, Secretary.
- American College of Surgeons, Chicago, Oct. 21-25. Dr. Frederic A. Besley, 40 East Erie St., Chicago, Secretary.
- American Public Health Association, Detroit, Oct. 8-11. Dr. Reginald M. Atwater, 50 West 50th St., New York, Executive Secretary.
- American Roentgen Ray Society, Boston, Oct. 1-4. Dr. Carleton B. Peirce, Royal Victoria Hospital, Montreal, Canada, Secretary.
- American Society of Anesthetists, New York, Oct. 10. Dr. Paul M. Wood, 745 Fifth Avenue, New York, Secretary.
- American Society of Tropical Medicine, Louisville, Ky., Nov. 12-15. Dr. E. Harold Hinman, Malaria Control Division, Wilson Dam, Ala., Secretary.
- Association of Military Surgeons of the United States, Cleveland, Oct. 10-12. Dr. H. L. Gilchrist, Army Medical Museum, Washington, D. C., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Influence of Syphilis on Intelligence of Children. R. L. Jenkins, Warwick, N. Y.; A. W. Brown and Lillian E. Cisler, Chicago.—p. 341.

Clinical Picture of Tuberculosis in Children. Edith M. Lincoln, New York.—p. 371.

Acetylbetamethylcholine Bromide for Megacolon.—

Law states that the neurogenic theory of megacolon is supported by the clinical successes following interruption of the sympathetic nerves or the use of cholinergic drugs which inactivate the autonomic nervous system. Acetylcholine increases the parasympathetic nerve impulses and stimulates peristalsis of the colon. There is no record of the successful use of any cholinergic drug in the management of megacolon. As a remedial agent acetylcholine is limited because, although physiologically potent, its instability and its frequently alarming toxic effects discourage its use. Eight years ago Cowie carefully adjusted doses of acetylcholine and a derivative, acetylbetamethylcholine, and in combination with conservative medical measures designed to promote colonic movement caused an infant suffering from typical megacolon to recover completely. This served as a stimulus for the use of acetylcholine or its derivatives in the treatment of such disorders. Acetylbetamethylcholine bromide has the advantageous pharmacologic properties of acetylcholine but is more stable in the body and produces a definite and continued stimulation of the parasympathetic nerves, usually without untoward toxic manifestations. It slows the cardiac action, lowers blood pressure, dilates peripheral blood vessels, stimulates sweat glands and increases intestinal tone and peristalsis. It may constrict the bronchioles and incite an asthmatic attack, or in large doses it may produce abdominal pain and vomiting. Its effects can be abolished by the subcutaneous injection of $\frac{1}{400}$ grain (0.0001625 Gm.) of atropine sulfate. The drug is fairly stable in tablet form and is suitable for oral administration. With this preparation a method giving highly satisfactory results has been evolved since 1936 for the treatment of megacolon patients. The average initial dose of acetylbetamethylcholine bromide is 0.1 Gm., increased, if necessary, in two or three days to 0.2 Gm. and again after several days by the addition of 0.1 to 0.2 Gm. in midafternoon. Usually 0.2 Gm. after breakfast is effective without the afternoon dose. As the drug becomes effective (from five to ten days) enemas are discontinued, though liquid petrolatum is continued as a mild mechanical aid. When a dosage which produces one or two stools daily is determined, the patient is discharged, usually with instructions to take 0.2 Gm. of the drug one half hour after breakfast, from 1 to 2 tablespoons of

liquid petrolatum every evening and an enema in the event of constipation or distention. Recently prostigmine bromide has been used as an augmentor of acetylbetamethylcholine bromide, as it prevents the destruction of the active principle, acetylcholine, of the latter drug. In moderate dosage prostigmine is safe, it does not disturb blood pressure or heart action and its use may be beneficial. The author used derivatives of acetylcholine in the treatment of megacolon for the following groups of patients: those in whom satisfactory initial drug therapy was abandoned in favor of sympathectomy, those treated with subcutaneous injections for brief periods with little benefit, patients experiencing obstinate relapse after sympathectomy, which was relieved by drug therapy, and patients whose condition was successfully managed by medical therapy.

Banana and Banana Powder for Diarrhea.—Wolman and Roddy used mashed bananas or banana powder in the treatment of ninety-seven patients, from 1 week to 10 years of age, suffering from diarrhea. The results are compared with a control group of eighty similar children treated by a variety of recognized therapies. Diarrhea was defined as the passage of loose, watery, mucopurulent or bloody stools, usually with an increase in frequency and persisting for longer than twenty-four hours. The diarrheas were classified as specific, parenteral and unknown. The outcome was considered good if complete recovery had taken place by the end of a week. Forty-nine of the eighty control patients and fifty-four of the treated group were less than 1 year of age. In the control group recovery was good among seventeen parenteral, sixteen unknown and twenty specific diarrheas; the respective poor recoveries were five, eight and eleven. Among the banana diet group of patients thirteen with parenteral, thirty with unknown and twenty with specific diarrheas had good recoveries, while five, eleven and fourteen had poor recoveries. There were three deaths among the control and four among the banana diet group of children. There were no significant differences within the two groups as regards age, etiologic factors, severity of infections, state of nutrition and mortality rates. Banana feeding was as effective as the older and more usual feeding regimens. It was well taken and the patients receiving it were usually relieved of hunger, tenesmus and abdominal discomfort and passed semiformal stools.

Sorbitol as Dehydrating Agent.—According to Browder and Bragdon, sorbitol, a modified monosaccharide ($C_{12}H_{22}O_{11}$) derived from the reduction of dextrose and levulose, may be employed as an osmotic dehydrating agent and diuretic. The

authors investigated its effect on the cerebrospinal fluid pressure, pulse, respiration, blood pressure and psychologic state in persons with and without disease of the central nervous system. Thirty-three patients with various diseases of the intracranial structures were studied, with five patients as controls who had neither clinical evidence of a pathologic process implicating the nervous system nor increase in the intracranial tension as measured by the cerebrospinal fluid pressure. A total of fifty intravenous injections of sorbitol was given to thirty-eight patients. Clinical improvement as evidenced by a more lucid state of consciousness and relief of headache was noted in 54 per cent. Detailed observations concerning the cerebrospinal fluid pressure, pulse, blood pressure, respirations and psychologic state were recorded in ten experiments. Included in the detailed studies were two patients without evidence of disease of the central nervous system. In each experiment on the two subjects a slight reduction in cerebrospinal fluid pressure was effected and sustained for more than two hours. In four of the five patients in whom an elevation in cerebrospinal fluid tension was demonstrated, the injection of sorbitol produced an immediate reduction in the pressure followed by a secondary rise to a level higher than that observed prior to the injection. In a patient who had sustained a recent craniocerebral trauma there was an immediate progressive rise in cerebrospinal fluid pressure to twice the original level following the injection. The authors conclude that in general the action of sorbitol as measured by the reduction in cerebrospinal fluid pressure is comparable to dextrose but less satisfactory than sucrose. The frequent occurrence of chills following the intravenous injection of this chemical militates against its use as a dehydrating agent.

Mesenteric Venous Occlusion.—According to Brown the literature contains reports of 772 cases of mesenteric vascular occlusion, most of them arterial occlusion. The author believes that venous occlusion is a separate clinical entity. This study was made in 101 cases of venous occlusion taken from the literature, two from the Guthrie Clinic and one from the author's practice. Seventy-one of the 104 had a fatal outcome. Of the patients who recovered, 57.5 per cent had been ill for nearly two weeks before operation. This does not support the calculations of Warren and Eberhard that the mortality rate increases from 25 per cent in the first twelve hours to 83.3 per cent after four days. An investigation on the relationship of the extent of the involved mesentery and intestine to the outcome of the disorder revealed that the average length of the bowel involved in twenty-two of thirty-three patients who recovered was 38 1/4 inches. Of thirty-seven patients who died, an average of 102 1/2 inches of the intestine was infarcted. It is generally conceded that symptoms of arterial occlusion are fulminating and those of the venous type are less so. The onset of pain may be rapid or slow. It may be colicky. The contrast between the severity and persistence of the pain and the paucity of physical observations was the most significant diagnostic feature of mesenteric venous occlusion. Vomiting is more frequent in the arterial than in the venous lesion. Constipation is considered more common than diarrhea. Distention is regarded by most observers as a late manifestation and is not relieved by bowel movement or enemas. Shock is considerable in fulminating cases and is proportional to the degree of mesenteric involvement. The temperature at the onset is either normal or subnormal but within a few hours may rise to 103 F. The pulse rate may be slow at the onset but varies with the temperature and degree of shock. Patients with a rapid onset and severe pain will show varying degrees of pallor, but patients with venous thrombosis and a slow insidious onset may show no complexion changes until the occlusion becomes complete and the epigastric pain severe. Tenderness is much less than would be expected in proportion to the pain and extent of the lesion. There is a general abdominal tenderness without localization, especially in the venous cases, until the occlusion becomes complete. The tenderness in the advanced cases tends to be epigastric. Rigidity is generally lacking in the early cases, but as the lesion advances it becomes more definite. Peristaltic sounds are not likely to be so loud and gurgling as in cases of mechanical obstruction, but, when the entire small bowel is affected by the thrombotic process, absence of peristaltic sounds is the rule and distention is more likely to occur. There may be no evidence of gross blood in

the stools but laboratory tests would undoubtedly show its presence more often than is reported. At the onset the white blood count may be normal, but as the lesion progresses leukocytosis is the rule. X-ray examination of the abdomen can be expected to show evidence of intestinal obstruction in a large percentage of cases. Although enterostomy has been advocated by some, most writers agree that primary resection of the involved portion of the intestine is preferable. It has been pointed out that resection of from 3 to 6 inches on either side of the area of infarction is necessary to prevent extension of thrombosis. In cases due to overindulgence in alcohol, resection may not be necessary to effect a cure. In cases in which thrombosis results from infection such as appendicitis, Jones advocates the Wilms-Braun operation of ligation of the ileocolic vein to prevent the extension of thrombosis. The author reports histories of three typical cases.

Diphtheria Immunization.—Worden points out that at the Alexandra Hospital for infectious diseases in Montreal it has been the routine to record on admission whether that patient had or had not been immunized to diphtheria. The 9,295 admissions to the hospital from 1932 to 1938 inclusive were studied with reference to diphtheria immunization. The patients were suffering from scarlet fever, measles, diphtheria, whooping cough, parotitis, chickenpox and erysipelas. Of all the patients less

than 12 years of age who made up 80 per cent of the admissions admitted in 1932, 16.9 per cent had been immunized. This figure rose to 53.5 per cent in 1938. In 1938 only 9 per cent of all children less than 1 year of age and only 25 per cent of those less than 2 years of age had been immunized. In Montreal in 1933 there were 297 cases of diphtheria with eighteen deaths and in 1938 there were 227 cases and twenty-six deaths. Immunization of infants at the age of 6 months should be particularly encouraged and this should be followed by a further dose of toxoid at about 5 years of age. Diphtheria does occur among patients who have had a full immunization course. There have been four such cases at the Alexandra Hospital during the last three years. These cases probably fall into that group of children who after three or four years require "reimmunization" with a single dose of toxoid (from 0.25 to 1 cc.).

Osteoid Osteoma.—Jaffe stated in 1935 that osteoid osteoma began its development in the spongy bone. Jaffe and Lichtenstein show that it can originate also, if not within the substance of bone cortex, at least on its periosteal or medullary surface. Their present thirty-three cases include thirteen instances in which the lesion developed in the shaft cortex of a long bone. These lesions, like those in spongy osseous areas, were misinterpreted as instances of chronic osteomyelitis or of osseous abscess. More particularly the cases in which the lesion was in the shaft cortex had been misclassified as representing so-called "sclerosing nonsuppurative osteomyelitis" or else "intracortical bone

abscess." The authors interpret this lesion anatomically as a benign osseous neoplasm. They believe that a great many cases which in the past have been interpreted as osteomyelitis with annular sequestrum, chronic bone abscess, osteomyelitis with cortical osseous abscess, sclerosing nonsuppurative osteomyelitis, osteomyelitis chronic from the beginning and the like actually belong in the category of osteoid osteoma. That is, they have as their common anatomic basis a distinctive benign osteoid and bone-forming tumor of slow and limited growth which in the course of its development may provoke reactive perifocal new bone formation, sometimes of considerable extent. Much of the misunderstanding of the condition has resulted from concentrating attention on this perifocal reaction instead of on the lesion proper. Unless the latter is removed (preferably intact in its bed of bone) and submitted for microscopic study, the true significance of the case may be missed, as it usually is. The osteoid osteoma proper is usually indicated roentgenographically by a relatively radiolucent or rarefied area or, if it has become substantially ossified, it may appear as a relatively radiopaque nidus. In the cortex of a long bone it may be difficult to distinguish the shadow of the osteoid osteoma if the reactive cortical thickening is considerable or if the lesion has become ossified, as its shadow may be dominated by that of the thickened cortex. Because the roentgenogram has these two aspects, cases are incorrectly labeled. The disorder has a predilection for adolescents and young adults, principally from 10 to 25 years of age. The presenting symptom is localized pain of at least several months' duration. Surgical excision of osteoid osteoma with some of the surrounding bone resulted in clinical cure with prompt and often dramatic relief of distressing pain. During their experience of seven years they have encountered no recurrences.

Pyelonephritis and Hypertension.—According to Crabtree, the demonstration that in about one half of the patients who die of hypertension pyelonephritic changes are found at necropsy, the clarification (through animal research) of the problem of deleterious effects of injured renal tissue in producing hypertension through some blood-borne substance that is elaborated by the diseased kidney and the recent recognition of an improvement in blood pressure following nephrectomy for chronic renal infectious disease have stimulated the study of renal deficiency and hypertension. The immediate result has been a rush to apply the new information with the danger that renal tissue that can ill be spared may be sacrificed. Aside from the clinical cases whose final fate is not yet known, evidence to support destruction of a portion of the renal tissue of a hypertensive patient is based only on animal experimentation and necropsy. The entire history of pyelonephritis has not yet been adequately covered by clinical surveys to indicate what have been the health conditions and the duration of life of affected patients. The author agrees with those observers who consider pyelonephritis a progressive disease of slow development, the end result of which is not apparent for many years, and that the apparent recovery from the acute phase of the disease is misleading. Blood pressure readings for thirty cases of severe pregnancy pyelonephritis from ten to eighteen years between the infection and the survey reveal that: 1. Seven cases which were intensively studied showed severe degrees of renal damage, as indicated by intravenous phenolsulfonphthalein excretion, intravenous pyelography, urea clearance-concentration and dilution tests, and nonprotein nitrogen determinations. 2. Only two of the thirty patients showed hypertension. One of them, who had a normal blood pressure at the time of the study, has since shown hypertension after a summer of athletic activity. 3. Hypertensive tendencies among the seven patients intensively studied were not in proportion to the degree of renal deficiency demonstrated at the stage of the natural history of pyelonephritis at which the study was made. 4. Hypertension is not the rule in severely injured pregnancy kidneys after a lapse of ten or more years from the initial injury of patients who show reasonable degrees of health. This does not imply that these patients may not be hypertensive at some later date. A study of forty-five patients examined from five to ten years after the initial injury (the pregnancy infection) revealed that: 1. Many of the patients showed evidences of renal damage, even though no pus, albumin or infection was present. 2. There are evidences of renal damage following the initial infection in all types of patients. There may have been a slight preponderance of such damage in the severe group. In a few cases labeled mild, the renal damage was most severe. 3. Of three patients whose pyelo-

nephritis was complicated by toxemia two were dead at five years and the other showed marked evidence of renal deficiency with hypertension. 4. Nonprotein nitrogen readings were elevated only among the toxic patients. 5. The excretion of intravenously administered phenolsulfonphthalein showed that excretion was delayed in the second and third fifteen minute intervals. The result was flattening of the normal curve. The first fifteen minute output was usually below 25 per cent. Total excretion for an hour was usually normal. 6. The ability to concentrate the urine was subnormal for the group. The urine of only seven patients could be concentrated to 1,025. 7. All patients with pyelonephritis who had toxemia and six without complications showed hypertension at the time of the examination. 8. Five of the forty-five patients had renal stones. 9. In four instances there was such poor filling of the pelvis and ureters that intravenous urography did not demonstrate the condition of the tract. One or both kidneys of five patients showed irregularity of the calices suggestive of contracture of the cortex. Inflammatory changes in the pelvis and ureters were common. 10. Total renal deficiency was present in seven of the eleven cases studied.

Prophylaxis and Medical Management of Calcium Urolithiasis.—Flocks states that previous work emphasized the importance and significance of the role of urinary calcium in the pathogenesis of calcium urolithiasis and indicated that the latter condition was to be modified depending on the urinary calcium. It was shown that the normal daily urinary calcium is approximately from 90 to 150 mg. on a neutral ash diet which is low in calcium and phosphorus. Marked increase in the intake of calcium and phosphorus raises the urinary calcium to from 300 to 350 mg. daily. Acid ash diets or increased vitamin D intake bring about only slight rises in the urinary calcium of the normal individual. However, certain changes in the body mechanism (body immobilization, the early stages of certain bone conditions, hyperthyroidism, hyperparathyroidism and early intrinsic renal changes) are associated with increased urinary calcium excretion. There is a large group of individuals in whom the exact cause of high urinary calcium excretion is undetermined. These individuals make up approximately 60 per cent of patients with calcium stones. Marked intrinsic renal damage, the later stages of certain bone diseases and hypoparathyroidism present low urinary calcium excretions. On the basis of studies on the quantitative variations in urinary calcium excretion and the finding that large fluid intake lowered the urinary calcium concentration without significantly altering the daily urinary calcium excretion, regimens for the prophylaxis and medical management of calcium urolithiasis were outlined. They depended on (1) ruling out and treating all other factors present, (2) determining the urinary calcium excretion, (3) if the urinary calcium was high, searching for and removing the cause if possible; forcing fluids to lower urinary calcium concentration, giving relatively low calcium and phosphorus intake, using acid ash diets and vitamin D intake with caution since increased urinary calcium resulting from their use counteracts the beneficial actions of lowered urinary pH , avoiding urinary tract infection and when the urinary calcium returns to a normal or low value getting rid of any stone nuclei which may have been formed by placing the patient on a special regimen and (4) if the urinary calcium is low or normal forcing fluids to lower the urinary calcium concentration and using an acid ash diet and acidifying drugs if lowering of the urinary pH is obtained. The author felt that a more thorough knowledge of the effect of treatment on the urinary calcium precipitability was necessary before more satisfactory results could be obtained and reasons for failures ascertained. The amount of calcium salts that will precipitate from any given sample of urine will vary according to many factors, but it can be determined rather roughly by the following method: One hundred cc. of freshly voided urine is divided into two portions after the pH has been determined. In one the concentration of calcium is obtained and the other is thoroughly mixed with 1 Gm. of finely divided calcium phosphate for ten minutes, filtered and the calcium concentration obtained. The two concentrations are then compared. The urinary calcium precipitability is then expressed as minus the milligrams of calcium which will precipitate from the urine when it is mixed with calcium

phosphate. A minus value indicates that calcium will precipitate from the urine and a positive value that calcium phosphate will dissolve in the urine under these conditions. Studies of this type have been carried out on nineteen normal individuals and five patients with renal stone. The urine of the normal individual under normal conditions has shown a precipitability of from minus 2 to 8. When the calcium intake has been lowered and the urine concentrated this has been changed to a plus 1 to 3. In contrast the precipitability values of a patient with many stones were from minus 11 to 16. Dilution lowered the precipitability but never changed it to a plus quantity. Thus far the method has proved valuable in evaluating the significance of urinary calcium precipitability in calcium urolithiasis and in studying and following the effects of therapy.

Erysipelas: Sulfanilamide Treatment.—Beginning with May 1937 and extending to April 1, 1939, Top and his associates treated cases of erysipelas admitted to their hospital with sulfanilamide. They compare these with cases treated with antitoxin during a period of about the same length just prior to May 1937. The number of patients treated with antitoxin was seventy-six and the number treated with sulfanilamide was 135. They observed that the proportion of cases that showed no spread was twice as great among those treated with sulfanilamide as among those given antitoxin. The proportion of cases with slight spread was about the same for the two groups, but moderate spread was noted twice as frequently among the antitoxin treated as among the sulfanilamide treated. Marked spread was noted among 10.5 per cent of antitoxin treated, whereas none of the patients receiving sulfanilamide showed this degree of extension. A marked difference was noted in the number of febrile days following institution of treatment with antitoxin or sulfanilamide. The average number was 6.1 days for the former compared to 2.6 days for the latter. The number of days in the hospital for the antitoxin treated group was 14.3 days and for the sulfanilamide treated group 7.5 days. This difference is a distinct advantage to the patient and his purse. In a hospital where a vast majority of patients are indigent or semi-indigent, the saving in the cost of hospitalization to the city is tremendous. The proportion of complications occurring in the antitoxin treated cases was 21.1, compared to 11.3 in the sulfanilamide treated group. If two accidental deaths were removed from the sulfanilamide group, the fatality rates for the antitoxin and sulfanilamide groups would be about the same. It is remarkable that no infant has died since sulfanilamide has replaced antitoxin. The dose of sulfanilamide used in the

treatment of erysipelas is comparatively small. About one half to three fourths of a grain of sulfanilamide per pound of body weight daily is administered for a period of from four to six days. This amount rarely gives a blood sulfanilamide level exceeding 5 mg. per hundred cubic centimeters. A large initial dose consisting of one third of the daily dose may be given at four hour intervals day and night. Infants demand slightly higher amounts per unit of body weight. Elderly persons must be carefully watched because kidney elimination may be impaired. The blood picture should be closely followed and a complete blood count should be made every other day. The authors conclude that the use of sulfanilamide has proved of distinct value in the treatment of erysipelas.

Transportation of the Wounded by Plane.—According to Schmidt, German ambulance planes have been put into operation in appreciable number on the Eastern Front. The traveling speed of the large medical planes is 230 kilometers an hour. In contradistinction to all land transportation the plane maintains its speed without interruptions from takeoff to landing. Airplane transportation is superior to all other methods, because, while flying, jarring of the patient rarely causes pain and the transportation time is short. If taking the wounded to and from the flying field could be disregarded, the limits to the possibilities for air transportation could be widened even further than was actually the case in Poland. The trimotor passenger plane as an ambulance plane must be considered a lucky choice. Four removable stretcher racks in the open space in the cabin carried eight stretchers. The racks are fastened rigidly to the wall of the plane and permit no motion in any direction, except for elasticity. No necessity for springs has been felt either in squalls while in flight or when landing. Short leather straps keep the stretchers from slipping. Lying in pairs, one beside or above the other, each patient is easily reached from the central aisle. There is enough room to change a bandage while in flight, observe the patient's face, pass refreshments or give injections. The attending physician finds a good supply of syringes and cardiac and sedative preparations, also a dressing kit, sterile gauze, splints and padding material. The relatively large number of spinal injuries has made it necessary to include rubber or glass bedpans. They are now standard ambulance equipment. Since the wounded are very susceptible to cold, the planes are equipped with cabin heat of the same type used in passenger planes. Combining several airplanes in one medical unit was found expedient. The greatest difficulty of airplane transportation is that the ambulance plane requires suitable landing and takeoff fields and is dependent on land means of transportation. At the flying fields much time was wasted with waiting and loading after the plane had landed. Such delays are avoidable if the probable time of landing is reported in advance to those at the front. For carrying communications in the area between the rear of the front section and temporary air stations for large planes, a small scout plane would be most adequate. Such a plane could restore broken connections in the shortest time, receive new orders, pick out the most suitable open fields in the closest proximity to the wounded and in cases of emergency, if the plane is adapted to it, could pick up one or two severely wounded. The author asserts that not a single wounded man transported by himself in a reclining position has ever suffered airsickness, notwithstanding squalls during several flights. The reason for this lies mainly in the fact of the reclining position of the body, the short duration of the trip and

the avoidance of marked turbulent air currents in the proximity of the ground up to 400 meters. Wounded soldiers have felt very grateful for the airplane transportation. Many soldiers looked on transport of 400 kilometers, to their home base in two hours, as incredible. Great elation was felt over this type of care of the wounded and even among those left behind it created the feeling that everything possible was being done even for the common soldier. The morale of the soldiers is thereby maintained.

Renal Factor in Continued Arterial Hypertension.—

According to Palmer and his associates, removal of the affected kidney of a number of patients with unilateral renal disease associated with hypertension has had a marked and beneficial effect on the blood pressure. During the last four years the authors included genito-urinary studies in the survey of their cases of essential hypertension, but they confined this study mostly to patients under 50 and they included at least one intravenous pyelogram in all new cases. Of 596 patients diagnosed as having essential hypertension, intravenous pyelograms were taken in 212. Forty-seven (22 per cent) of 212 patients with continued arterial hypertension not due to glomerulonephritis showed congenital or acquired deformities of the pelvis or ureters by urography. The deformity in the pyelogram was unilateral in thirty-four (72 per cent) of these forty-seven cases, or 16 per cent of the 212 cases studied. Such deformities are often incidental but, if significant in the etiology of the hypertension, probably represent a participating or precipitating, rather than a major, factor. Various urologic lesions are observed over long periods without the development of hypertension. Continued arterial hypertension is a fairly common occurrence and the coincidental presence of a certain number of the commoner urologic lesions is likely. The comparative incidence of hypertension and urologic lesions should be studied in the general population. Weiss and Parker believe that chronic infection affects the arterioles in some way so as to bring about a hyperplastic intimal change, which in turn causes ischemia and hypertension. This intimal hyperplastic change, according to

Weiss and Parker, after leading to luminal narrowing or even obliteration, is the sine qua non of hypertension in cases of pyelonephritis. When these criteria are applied to the cases discussed in this paper, only two show changes consistent with true hypertensive pyelonephritis. They both showed marked arteriolar hyperplastic changes, lymphocytic infiltration and colloid casts in the tubules. The fact that one of these two cases has been much improved by nephrectomy suggests that the arteriolar hyperplastic change assumes a dominant role in the production of hypertension. That the other case did not respond may possibly be explained by Weiss and Parker's theory that the nephrectomy had been done after the vicious circle—pyelonephritis leading to hypertension, which in turn leads to vascular nephritis in the other kidney—had been established. In considering nephrectomy, the age of the patient and the duration of the hypertension should be considered. In general, it may be said that one should not advise nephrectomy for a unilateral renal lesion when associated with hypertension in women over 45 or men over 50. The factor of congenital predisposition should not be overlooked among patients with continued arterial hypertension. Patients with chronic pyelonephritis, both active and inactive, and those with lesions obstructing the urinary outflow have been followed for many years without the appearance of continued arterial hypertension. The difference between these patients and those with similar urologic lesions and also continued arterial hypertension may lie in the degree of congenital predisposition. The decision to remove the affected kidney, with the hope of curing or modifying the course of the hypertension, is based on three assumptions: that the lesion is not incidental, that there is no vascular disease in the remaining kidney and that there will not be recurrent pyelitis in the remaining kidney.

Etiologic Indications of Early Gastric Cancer.—Ewing discusses gastric cancer from the morphogenic point of view. He admits that this is medical speculation but hopes that it may suggest something of the etiology of early gastric cancer. Certain constitutional factors which may influence its incidence, such as heredity, must be eliminated. Early gastric cancers appear in several varied forms which suggest entirely different modes of origin and exciting agents. Therefore any attempt to simplify their causation is likely to fail. 1. Congenital abnormalities (misplaced portions of gastric or intestinal mucosa and tissue rests of the pancreas and adrenal) give rise to a small proportion of gastric cancers. For the development of these cancers it seems unnecessary to introduce other factors than those inherent in the growth potentialities of misplaced and embryonal cells. 2. A number of gastric cancers develop on polypoid adenomas. The etiologic problem is identical with that of gastrointestinal polyposis. Here a notable hereditary element, in addition to a special susceptibility of the mucosa to react to chemical irritation or infection by atypical changes in the superficial cells and polypoid outgrowths, exists. This group of cases invites investigation of the chemical and bacterial character of the gastric contents. 3. Another group of gastric cancer is combined with pernicious anemia. Usually a small tumor arises in an atrophic mucosa and an atrophic stomach, and both are the results of the atrophic gastritis. The ultimate etiology must be traced back to the causes of atrophic gastritis. 4. The relations between ulcer and cancer of the stomach are rather close, quite obscure and as yet unexplained. These cases present multiple lesions, usually in association with hypertrophic gastritis and sometimes with an atrophic mucosa. Excavation of a gastric adenocarcinoma, giving rise to ulcer and cancer in the same stomach, has been demonstrated. Under these conditions the appearance of precancerous changes on the edges of the ulcer can be accounted for, but these precancerous or preulcerous lesions would not be the result of the ulcer but the cause of the ulcer. Such lesions, if they escaped ulceration, owing to low digestive activity, would go on to fully developed cancer, whereas, if digestive activity were high, ulceration would supervene and the lesion would become a peptic ulcer. Gastric ulcers do not all arise in this manner, but it seems probable that some do, explaining some of the peculiar combinations and assumed transformations between ulcer and cancer in hypertrophic gastritis. An active cancerigenic agent is sug-

gested in such cases. A possible relation to avitaminosis should be considered and the gastric mucosa in cases of the Plummer-Vinson syndrome should be studied. 5. Pyogenic infection cannot stand as a specific cancerigenic agent but it does figure in the appearance of carcinoma in chronically infected wounds. While bacterial infection may probably not be included among the direct exciting causes of gastric cancer, it should not be neglected as a contributing cause which affects its course. 6. The gastric cancer which arises exclusively from the chief cells lining the fundi of the glands while the duct cells remain intact produces most of the cellular small cell diffusely growing and highly malignant gastric carcinomas. Some functional stimulus affecting the functioning cells of the glands seems to be a reasonable hypothesis. The great frequency of gastric cancer is not surprising. The organ is exposed to the mechanical burden of excessive quantities of food and drink, to wide variations of heat and cold, to a multitude of chemical irritants in the ingestants, to insults from powerful medicaments, to a multitude of pathogenic and saprophytic bacteria and to regurgitation of foreign digestants in bile and pancreatic fluids, and at the same time it is required to maintain nearly constant functional activity.

Gastroscopic Observations After Operation.—Moersch and Walters review gastroscopic observations on 100 patients who had undergone operations on the stomach and who subsequently developed gastric distress. They concluded that gastroscopy can be of assistance in reaching a better understanding of the factors leading to gastric distress after operations on the stomach. Contrary to the commonly accepted teaching that gastritis is found in all stomachs after operation, in 30 per cent of these cases of persistent dyspepsia gastroscopic evidence of disease was not present. As a rule, in the cases in which abnormality of the gastric mucosa was not demonstrated by gastroscopy the functional factor was found to be rather pronounced, and most patients responded symptomatically to therapeutic measures directed to this end. The diagnosis of gastritis was made on gastroscopic observations in fifty-six cases. In contrast to the cases in which gastroscopy revealed normal gastric mucosa the response to medical management was not as satisfactory, and further operation was frequently required. Postoperative gastritis may be thought to be a manifestation of gastritis that existed before operation. This is often true, and many postoperative complications might be avoided if this possibility was always recognized before operation. On the other hand, it is known that gastritis does develop after operation and also that gastritis which is present before operation may disappear after operation. That gastritis undoubtedly does develop after operation is seen from the fact that evidence of gastritis was present in 56 per cent of the cases in this study. In comparison, Swalm, Jackson and Morrison found gastritis in only 35 per cent of their routine gastroscopic examinations, and Schindler reported an incidence of 41.8 per cent. Speculating about the possible factors responsible for postoperative gastritis, the authors suggest that no doubt in many cases a preexisting gastritis is the responsible factor. In their opinion a poorly placed stoma with inadequate drainage of the stomach is an important factor. Gastritis is not as likely to develop if the stoma retains an activity resembling that of a sphincter. Infection constitutes an important exciting factor. Other lesions, such as gastrojejunal ulcer, carcinoma, gastric ulcer and benign tumor, can and do develop in the stomach after operation, and gastroscopy may be of assistance in their recognition. In five cases in this series carcinoma of the stomach was found on gastroscopic examination and in six cases gastrojejunal ulcer was visualized.

Inadequacy of Methods for Early Diagnosis of Gastric Carcinoma.—Abrahamson and Hinton state that during the last two decades—1919 to 1938 inclusive—444 patients with cancer of the stomach were admitted to the Fourth Division of Bellevue Hospital. Of these 296, or two thirds, were inoperable on admission. After clinical and x-ray examination 148, or one third, were considered operable. However, even in this group exploratory laparotomy proved in sixty-nine cases that no operative measure could be undertaken. In only twenty-four cases, or 5.4 per cent of the total and 16.2 per cent of the 148 operable cases, could gastric resection be done, the only method providing hope for affecting a permanent cure in gastric carcinoma. Thus the outlook is at present a dismal one, since the largest number of cases in which the diagnosis is made are already in an inoperable stage. Often when operability still exists, resectability is impossible. The most dependable confirmations of diagnosis are the x-rays, the gastroscope and the gastric test meal. The latter is the simplest and may be repeated at frequent intervals at relatively little expense. When examination shows a declining gastric acidity, the suspicion of carcinoma must be entertained and disproved. X-ray studies of the stomach should be made with greater frequency in suggestive cases and in those with undiagnosed and vague manifestations. X-ray examination of these patients is necessary, not to verify an already made clinical diagnosis, but for careful search where there is no evidence or only minimal evidence of gastric disturbance. The technic of gastric resection has been perfected and further operative refinements cannot offer hope for lengthening the life span of patients with gastric carcinoma. Their hope resides in the development of a means of diagnosis which will permit surgical intervention when the lesion is pathologically young rather than early in the clinical course. Until more specific tests are developed, each patient should have the benefit of such methods as are at our disposal. Faithful use of the test meal, the x-rays and the gastroscope may help to disclose early carcinomatous lesions. The knowledge of the present dark outlook for the patient with carcinoma of the stomach should be disseminated among all practitioners and students of medicine.

Surgical Treatment of Coronary Disease.—It has been suggested that the similarity of arteriosclerotic disease of the coronary arteries and of the extremities should permit of the application in the heart of surgical methods found useful in the treatment of peripheral vascular disease. Fauteux describes experiments on dogs undertaken to observe the effect of a partial coronary arteriectomy of the ramus descendens and a partial coronary arteriectomy of the same arterial trunk combined with ligation of the vena magna cordis. A high mortality resulted when partial resection of the ramus descendens at a high level was done. When the same procedure was carried out after venous ligation, all dogs, apart from those dying of operative complications and intercurrent disease, remained healthy for over a year. The author concluded that vena magna cordis ligation in occlusion of the left ramus descendens helps to maintain adequate coronary circulation after partial coronary arteriectomy. The results of these experiments suggest that in properly selected cases coronary vein ligation may be expected to act as a preventive measure against a second attack of coronary thrombosis and also to improve the coronary circulation sufficiently to relieve the pain of "angina of effort." It seems a logical procedure in traumatic surgery of the heart whenever it is necessary to ligate an important coronary arterial branch that is bleeding.

Preserved Blood.—On the basis of 1,364 bottles of stored blood, Edwards and Davie sought to determine the therapeutic value of stored blood as compared with that of fresh blood, and the extent to which its availability, standardization of technic and convenience of administration outweighed possible disadvantages. A number of hospitals cooperated in the investigation. Banked blood used by them was preserved in a 3.8 per cent solution of sodium citrate, the unit consisting of 450 cc., of which 45 cc. represented the anticoagulant solution. An apparatus of recent manufacture, supplied with an internal filter of glass shot that prevents clogging of needles and filters and allows storage bottles to remain closed at all times, was used. The blood withdrawing and delivery apparatus together with the "veinseeker" in cases of collapsed veins are illustrated. Wastage of bank blood, about 9 per cent in 1,500 bottles, was due to hemolysis or to accidents, such as overheating of blood and failure to return unused blood immediately to the refrigerator. The investigators noted in comparative transfusions with both fresh citrated and preserved blood that reactions due to the administration of banked blood were probably no greater than those due to fresh blood. Of 1,364 bottles of banked blood sixty-nine (5 per cent) gave rise to grade 3 reaction (definite rigor) with cases of acute posthemorrhagic anemia, chronic secondary anemia and acute septic conditions leading. However, no serious or permanent ill effects were observed. No case of transmitted disease occurred and no definitely infected bottle was found. Five deaths occurred during transfusion of patients who were moribund before transfusion. Of seventy-one patients who died soon after the transfusions only one showed rigor, a child with streptococcal septicemia. In many of these cases, transfusion apparently was a counsel of desperation, for the majority suffered from some disease of severe character. Of all transfusions, 87.5 per cent were considered to be of benefit to the patients. As a life saving measure in cases of acute hemorrhage with or without shock, preserved blood was as efficacious as fresh blood. Of 509 transfusions given for acute hemorrhage, 463 (91 per cent) were considered to be satisfactory. Likewise, in 316 transfusions given for chronic secondary anemia 292 (92 per cent) were regarded in the same way. The authors believe that in the presence of these diseases the ready availability of stored blood in bulk marks a true advance over the individual donor system. For certain other diseases of the hemopoietic system and for cases of anemia associated with sepsis, they regard fresh blood as preferable. They emphasize the importance of absolute correct grouping, the complete cleanliness of all apparatus and the elimination of all pyrogenic factors in the diluent solution. Since grade 3 reactions, were undoubtedly increased by the age of the blood, they advise against the use of blood older than ten days.

Thoracoscopy of Extrapleural Pneumothorax.—Maxwell states that, although the walls of an extrapleural pneumothorax may be dry at the completion of pneumolysis, a greater or lesser amount of oozing invariably occurs afterward. Schmidt found

in a review of 200 cases that in a large proportion the pneumothorax space showed subsequently a tendency to obliterate. Roberts expressed the opinion that obliteration is less likely to take place if the blood clot is broken up and aspirated. This is done under thoracoscopic control. The author treated three cases in this way and examined a fourth with the thoracoscope two months after pneumolysis. He describes the endoscopic appearance of the extrapleural pneumothorax in which postoperative hemorrhage occurred. In the extrapleural pneumothoraces in which endoscopy was employed soon after pneumolysis, long stalactites of blood clot with their apexes free and pendulating, or cones already attached to the lung, were seen, either at the first survey or after the softer clot that covered them had been removed. The longer stalactites of fibrin have always been found arising from the anterior chest wall. None of them were attached to the lung. The posterior projections were broader and shorter, cone shaped or sugar-loaf shaped, and in both cases fixed to the posterior surface of the lung. The semiupright position in which patients are nursed and the tendency of the collapsed lung to fall back toward the paravertebral gutter explain the greater length of the anterior stalactites and the apparent paradox that the shorter posterior cones seem more frequently to adhere to the lung. The author points out that thoracoscopy has revealed that oblitative pleurisy in intrapleural pneumothorax is often a sequel to the organization and contraction of interpleural fibrin bands. A similar mechanism is probably at work in the obliterating extrapleural pneumothorax. The fibrin bands are the cones or stalactites.

Nonpulmonary Tuberculosis Caused by Bovine Tubercle Bacillus.—Mushatt isolated strains of tubercle bacilli from fifty hospitalized children up to 14 years of age with nonpulmonary tuberculosis: cervical adenitis, bone and joint disease, meningitis and primary abdominal tuberculosis. Most of the patients were members of working class families. Thirty-seven of the strains of tubercle bacilli were of the human type and seventeen of the bovine type. The gland and joint cases were largely abscesses from which pus was aspirated. Of the fourteen cases of cervical adenitis ten were caused by strains of the bovine type, and four of the twenty-two cases of bone and joint disease and three of twelve cases of meningitis were caused by bovine strains. Material from two cases of primary abdominal tuberculosis yielded human strains.

Penetrating Wounds of Chest.—Ryle reviews the records of penetrating wounds of the chest admitted under his care during 1917 at a casualty clearing station near Ypres. The patients totaled 130, and thirty (23 per cent) of them died. Since none were discharged to the base until shock, sepsis and hemorrhage were under control and they were judged fit for the long train journey, it is unlikely that there was a high toll of subsequent deaths. In four of the thirty fatal cases there were serious multiple wounds besides the chest wound; seven patients died within twenty-four hours of admission; in one

there was perforation of the gullet besides the lung and a tear in the aorta plugged with thrombus, the patient surviving to the third day; in five there was damage to diaphragm and liver or spleen. If a patient is admitted in bad condition not attributable to other wounds, the cause may be one of the three following: 1. A "leaking" or "sucking" hemothorax or pneumothorax, calling for immediate plugging with wet esul gauze and a firm pad with strapping or a binder. 2. A tension pneumothorax calling for relief with the needle. The author never saw this as a complication of a penetrating wound; it is more likely to follow a crush injury. 3. Penetration of the diaphragm by a fragment passing through the chest and lung with damage to one or more of the abdominal viscera. A "leaking" hemothorax usually shows a large entry or exit wound from which there is a considerable flow or trickle or rhythmic spouting of blood or bloody fluid. An audibly "sucking" or "open" pneumothorax explains itself and calls for similar immediate treatment. The further immediate treatment in all such cases is the usual treatment for shock or hemorrhage. The procedure in closed hemothorax, apart from appropriate nursing, postural measures and relief of dyspnea and pain, was to wait until the second day and then to needle and withdraw a syringe of blood. This should be examined with the naked eye and the nose. The change from the appearances of normal blood or bloody effusion to the more fluid and purple appearance of laked or hemolyzed blood is soon appreciated. While it remains unlaked and sweet there is no heavy anaerobic infection. In the presence of laking and smell the chest should be drained, and there is no need to await the bacteriologic report. According to the patient's condition and the temperature chart, subsequent needlings for inspection and culture are carried out on the third or fourth and, if necessary, on subsequent days. In patients with the graver "leaking" or "sucking" wounds of the chest who survive the first day or two surgical intervention will nearly always become necessary for purposes of drainage of an infected effusion, toilet of the wounds and comminuted ribs and, when feasible, removal of the foreign body. The time for such action must be determined by the conditions obtaining in each case. The author has no doubt that with earlier admissions and better treatment of hemorrhage and shock early intervention will be undertaken more often than it was in 1917 and that the primary operations with removal of fragments, repair and closure will become more usual and save lives. Such primary operations should never be undertaken unless the patient is likely to remain under close observation.

Alum Precipitated Toxoid in Diphtheria.—Faragó reports experiences with one-shot immunization with alum precipitated toxoid. His investigations were made on 22,000 children in Hungary. He found the Schick test reliable for mass control. The Schick toxin contained a fiftieth of a minimal lethal dose in 0.1 cc. and conformed to the demands set up by the permanent commission of biologic standardization of the League of Nations. The subjects tested were children who had been vaccinated by the one-shot method from one to five years previously and had never received any other diphtheria antigen; they had not even received the Schick test before. The purity of the precipitated and five times washed toxoid is about six times higher than that of the liquid toxoid. It contains about 2 mg. of alum and 47 protective units per cubic centimeter. The precipitate forms about a third of the total volume of the vaccine. The preparation of such a vaccine was justified by the observation that the formation of a depot, slow absorption and a more lasting antigen stimulus is promoted by an increased amount of the precipitate. The reactions produced by the alum precipitated toxoid were not more but rather less than those caused by the old fluid toxoid. The author tabulates separately the results for the age group from 2 to 6 years and from 7 to 11 years. The Schick test on children aged from 2 to 6 years who had received at the age of 2 their only vaccination against diphtheria in the form of 1 cc. of alum precipitated toxoid revealed that the immunity of children below school age is not ideal but, from the practical point of view, sufficient a year after vaccination. Afterward the immunity shows a slight tendency to fall, but the fall never reaches such proportions as to condemn the routine use of the one-shot method. About 80 per cent of the older children were vaccinated with alum

precipitated toxoid at the age of 7, and about 20 per cent from one to two years earlier. Results of Schick tests show that the immunity of this group surpasses that of the younger children. The immunity of children vaccinated at 2 and revaccinated at 7 also was investigated. The results in these may be regarded as the maximum of immunity that can be achieved by immunologic methods. The author concludes that an adequate immunity develops after one injection of alum precipitated toxoid and that this lasts for a sufficiently long period.

Artificial Tympanic Membrane in Comparison with Hearing Apparatus.—According to Nadoleczny-Millioud the artificial tympanic membrane is used only in defects of the tympanum or after radical operation, when the hardness of hearing is bilateral. It is hardly ever employed as long as one ear still has adequate hearing. It has the disadvantage of making the patient dependent on the otologist, who frequently has to change or readjust the membrane; moreover, he has to make it and fit it, because the tympanic prostheses obtainable on the market are rarely suitable. Occasionally the artificial tympanum irritates and produces secretion, but this is harmless and disappears quickly; the fear of recurrent suppuration is generally exaggerated. It should not prevent a trial with a tympanic prosthesis in cases in which it is indicated; that is, in all dry perforations or scars. It has one disadvantage in common with the hearing apparatus: noises which the patient did not hear before are now excessively loud. Because of this the patient at first may find it difficult to go to sleep. The artificial tympanum has several advantages: It is not visible from the outside, it causes practically no distortion and it does not make the patient more hard of hearing for some sounds than he is. The available electrical hearing devices do not transmit sounds undistorted. Another advantage of the artificial tympanum is the disappearance or the weakening of subjective sounds (tinnitus). There are two methods of estimating the value of a hearing prosthesis: The first is the exact quantitative and qualitative examination of the auditory capacity with and without the prosthesis; the second is the report of patients who have some knowledge of acoustics and of music and who observe themselves carefully. The author describes in detail the experiences of one patient who had undergone a bilateral radical operation and who had used not only several electrical hearing devices but also an artificial tympanum of silver-leaf. The patient asserted that the acoustic effect of the silver-leaf tympanum was comparable, although not quite equal, to that of a rather large and cumbersome (weight 9 Kg.) condenser-microphone, in which the loudness could be modified and which he used when attending meetings and lectures. The subjective effect of the artificial tympanum, however, is even better than that of the apparatus. It overcomes all self-consciousness because it makes strings and technical devices unne-

cessary. The patient has no difficulty in keeping up a conversation in a small group if the tympanum fits well. The ability to hear everyday noises has a beneficial psychological effect. The superiority of the artificial tympanum over other hearing aids is due chiefly to the faithful transmission of the high tones up to the fifth-marked octave. Artificial tympanums are now being made not only of silver-foil but also of cellophane. The fact that this hearing prosthesis is suitable for only certain patients is, in the belief of the author, no reason for neglecting it completely.

- *Vulvovaginal Moniliasis. F. Ruiz Arce.—p. 483.
Intraveneous Euparion Anesthesia in Minor Gynecologic Surgery. J. Gallucci.—p. 501.

Vulvovaginal Moniliasis.—Ruiz Arce reports ten cases of acute, subacute or chronic vulvovaginal moniliasis in young adult women, with the exception of one who was in the menopause. The patients were in good general, nutritional and hygienic condition. The duration of the infection varied from two months to three years, except one of thirteen years' duration. Three patients in the group had diabetes, three were pregnant, five presented venous engorgement of the pelvis manifested by varices of the saphenous vein and of the small vulval venules, hemorrhoids and engorgement of the local subcutaneous capillaries. A clinical diagnosis was made in the majority of the cases from the symptoms. Acute infection manifested itself by discharge, vulval pruritus intensified at night and before menstruation, pain and burning in the vagina during voiding, increase of local temperature and sometimes leukorrhea. The internal surfaces of the vulva and vagina were red, edematous and spotted with typical mycotic patches abundant at the lower part of the vagina. In some the neck of the uterus was involved. Chronic forms presented a typical appearance of dermatitis suggestive of early kraurosis or atrophic chronic vulvitis. Sometimes the vulva had the aspect of a so-called creamy vulva. The diagnosis was confirmed by smears and cultures from vaginal and vulval secretions. The smears were stained by the Gram method and the cultures grown on the Sabouraud medium. Any attempt to classify Monilia as to definite types is unnecessary for the purpose of a diagnosis. Monilia may be present alone or in association with bacteria. In one case the vaginal secretion contained Monilia and Trichomonas. Satisfactory results were obtained in all cases from daily topical application of a 2 per cent gentian violet solution.

- Recurrent Emphysematous Spontaneous Pneumothorax. M. R. Castex, E. S. Mazzei and J. M. Remolar.—p. 1475.
*Tuberculous Cavities of Lung. H. A. Passalacqua and M. O. Dunan.—p. 1491.

Suction Drainage of Tuberculous Cavities of Lung.—Passalacqua and Dunan emphasize the value of Monaldi's suction drainage of tuberculous cavities of the lung. Three cases are reported. The method consists of puncturing the cavity through the thoracic wall with a trocar, introducing a thin rubber catheter, fixing the external segment of the catheter to the thoracic wall and connecting its distal end to a system of continued siphonage. The site of the puncture and direction of the trocar are determined from the position of the cavity as ascertained by x-ray examination. The depth of introduction of the catheter is determined by the number of centimeters the trocar traverses from the thoracic wall to the cavity. The catheter is clamped for the first twenty-four hours if blood does not appear in the secretions removed by a syringe, and for two or three days if there is blood. On the day or days when the catheter is clamped, the clamp is released at intervals of from eight to twelve hours and the secretion is removed by aspiration with a syringe, after which the catheter is connected with the suction system. Continuous aspiration is maintained for the first few weeks, up to the time when the cavity collapses and expansion of tissues about the cavity is demonstrated in roentgenograms. The suction is then discontinued for a few hours a day, during meal time and sleep. Suction

is continued until healing of the cavity takes place. The process of healing of the cavity is paralleled by the improvement in the clinical symptoms and general condition of the patients. Fever and toxic symptoms disappear early in the course of treatment, the amount of sputum and secretion diminish and disappear, the tubercle bacilli disappear from both the secretion and the sputum, and the appetite and general condition of the patients improve. The proper position and functioning of the catheter are verified at intervals. If the catheter becomes obstructed, it is cleared by aspiration but never by insufflation of air. The catheter remains in the cavity for from two to five months. Removal of the catheter is determined by the healing of the cavity as demonstrated in roentgenograms. The channel left by the catheter heals spontaneously without formation of a fistula.

Fetal Adenoma of Thyroid in Child: Case. J. L. Monserrat and J. M. Pelliza.—p. 260.

*Acetarsone in Dementia Paralytica. N. G. Blaiotta.—p. 266.

Acetarsone in Dementia Paralytica.—Blaiotta reports fifteen unselected cases of dementia paralytica treated by subcutaneous injections of acetarsone and a bismuth compound. The injection, in a dose of 1 Gm. of acetarsone, was given three times a week in a series of twenty-one injections with intervals of a month and a month and a half, respectively, between the first three series and of two months between further series. Duration of the treatment was determined by the behavior of the cerebrospinal fluid. The latter showed favorable alteration by the end of the first or second series when the results of the treatment were satisfactory, except when paradoxical reactions took place. The bismuth preparation was administered in combination with the arsenical treatment as soon as favorable modification of the cerebrospinal fluid was noted. Twelve of the patients were given the arsenical and bismuth treatment alone, two patients were given the treatment one year after failure of malarial therapy and insufficient arsphenamine treatment, and for one patient, in an advanced stage of the disease, the treatment was changed to malarial therapy, which failed. The dementia forms with agitation or with megalomania were predominant in the group. Only one patient was ambulant. The remaining fourteen were kept in bed early in the course of the treatment. Of the group of patients treated by arsenic and the bismuth compound six had a complete remission, five resumed work and two discontinued treatment in the course of incomplete remissions. One patient exhibited a paradoxical reaction of the cerebrospinal fluid with cyclic delirium. Two patients had a physical and serologic improvement but the mental condition remained unchanged. One died from cachexia in the course of the treatment and the treatment of one failed. The two patients who had had malarial therapy improved. Twelve patients improved from the treatment, two died from dementia paralytica and the treatment of one failed. No complications occurred. The author concludes that the arsenical-bismuth therapy in dementia paralytica is effective and that blindness will not occur if proper indications and small doses evenly divided are adhered to.

Bacteriophage Therapy in Bacillary Dysentery.—The disappointing results with vaccine treatment of bacillary dysentery, according to Viskovskiy, are to be explained by the variability of bacilli of dysentery, as a result of which the polyvalent vaccine could not be definitely specific. The discovery of bacteriophage by d'Herelle made possible the preparation of a substance with a specific destructive effect on the

agent of bacillary dysentery. Viskovskiy reports on 3,549 patients with various forms of dysentery treated with bacteriophage in the course of the last three years. A control group of 5,398 patients were treated according to the orthodox regimen. The effect of the bacteriophage therapy is that of sterilization. It possesses no antitoxic property. For this reason the author adheres to the combined bacteriophage and serum therapy. The bacteriophage was given by mouth. Because the bacteriophage is completely inactivated by even traces of hydrochloric acid, the stomach contents must be evacuated prior to administration of the bacteriophage or the acidity neutralized by administration of from 10 to 15 cc. of a 5 per cent solution of soda. Bacteriophage therapy is effective only in the early days of the disease. It is without any effect after the fifth day because the predominant role at this stage is no longer assumed by the microbe but by the profound alterations which have taken place in the bowel, in the vegetative nervous system and in the metabolism. The bacteriophage is given in a repeated dose forty-eight hours after the first, or after twenty-four hours when the first dose has not given the expected clinical results. Comparison of the two groups showed that in the group treated by the bacteriophage there was no increase in the summer mortality, while in the control groups it rose from 2.8 per cent to 4.24 per cent. Mortality in the group due to the Shiga bacillus was lowered three and a half times as compared with the control group; in the group caused by Flexner bacillus twice, while in a group of 160 cases caused by the Kruse-Sonne organism there was only one death. The author concludes that, while the mode of action of the dysentery bacteriophage in a human organism has not been elucidated, the effect of its therapy is superior to any one measure so far advanced.

Specific Convalescent Serum in Infectious Mononucleosis.—Lassen and Thomsen report the successful use of specific convalescent serum in twelve cases of infectious mononucleosis, nearly all presenting severe angina with considerable lymph node enlargement, selected from a larger number serving as control groups. The serum was obtained from the blood of adult patients one or two weeks after they had become free from fever and was injected intravenously in total doses varying from 60 to 300 cc. The control groups were treated respectively with nonspecific serum (diphtheria antitoxin in forty-five of fifty cases), with neoarsphenamine or symptomatically with analgesics and antipyretics. One fourth (25 per cent) of the twelve cases showed a critical fall of temperature within twenty-four hours, an additional 50 per cent (six) within the first forty-eight hours. All twelve patients felt subjectively improved within twenty-four hours after the injections; eleven (92 per cent) exhibited a distinct objective improvement within the same period. No subsequent complications were noted, such as peritonsillar abscess or otitis. Comparably, in the largest control group preponderantly treated with diphtheria antitoxin only 34 per cent (seventeen) showed a fall of temperature within forty-eight hours and none within twenty-four hours, although the patients of this group had been given treatment twenty-four hours after hospitalization. Results such as those obtained in the twelve cases were observed in only a small number of the patients treated otherwise than by specific convalescent serum. Neoarsphenamine appeared to be ineffective although this group (twenty-seven) included cases of considerably milder attacks of the disease. The authors believe that infectious mononucleosis has not quite so favorable a prognosis as was formerly assumed and that a considerable number of cases may be masked as septic angina, malignant diphtheria or lesions of the central nervous system.
